

NEHRU COLLEGE OF ENGINEERING AND RESEARCH CENTRE (NAAC Accredited)

(Approved by AICTE, Affiliated to APJ Abdul Kalam Technological University, Kerala)

DEPARTMENT OF COMPUTER SCIENCE AND ENGINEERING

COURSE MATERIAL

CST 204 DATABASE MANAGEMENT SYSTEMS

VISION OF THE INSTITUTION

To mould true citizens who are millennium leaders and catalysts of change through excellence in education.

MISSION OF THE INSTITUTION

NCERC is committed to transform itself into a center of excellence in Learning and Research in Engineering and Frontier Technology and to impart quality education to mould technically competent citizens with moral integrity, social commitment and ethical values.

We intend to facilitate our students to assimilate the latest technological know-how and to imbibe discipline, culture and spiritually, and to mould them in to technological giants, dedicated research scientists and intellectual leaders of the country who can spread the beams of light and happiness among the poor and the underprivileged.

ABOUT DEPARTMENT

- ♦ Established in: 2002
- ♦ Courses offered : B.Tech in Computer Science and Engineering

M.Tech in Computer Science and Engineering

M.Tech in Cyber Security

- ♦ Approved by AICTE New Delhi and Accredited by NAAC
- ◆ Affiliated to the APJ Abdul Kalam Technological University.

DEPARTMENT VISION

Producing Highly Competent, Innovative and Ethical Computer Science and Engineering Professionals to facilitate continuous technological advancement.

DEPARTMENT MISSION

- 1. To Impart Quality Education by creative Teaching Learning Process
- To Promote cutting-edge Research and Development Process to solve real world problems with emerging technologies.
- 3. To Inculcate Entrepreneurship Skills among Students.
- 4. To cultivate Moral and Ethical Values in their Profession.

PROGRAMME EDUCATIONAL OBJECTIVES

- **PEO1:** Graduates will be able to Work and Contribute in the domains of Computer Science and Engineering through lifelong learning.
- **PEO2:** Graduates will be able to Analyse, design and development of novel Software Packages, Web Services, System Tools and Components as per needs and specifications.
- **PEO3:** Graduates will be able to demonstrate their ability to adapt to a rapidly changing environment by learning and applying new technologies.
- **PEO4:** Graduates will be able to adopt ethical attitudes, exhibit effective communication skills, Team workand leadership qualities.

PROGRAM OUTCOMES (POS)

Engineering Graduates will be able to:

- 1. **Engineering knowledge**: Apply the knowledge of mathematics, science, engineering fundamentals, and an engineering specialization to the solution of complex engineering problems.
- 2. **Problem analysis**: Identify, formulate, review research literature, and analyze complex engineering problems reaching substantiated conclusions using first principles of mathematics, natural sciences, and engineering sciences.
- 3. **Design/development of solutions**: Design solutions for complex engineering problems and design system components or processes that meet the specified needs with appropriate consideration for the public health and safety, and the cultural, societal, and environmental considerations.
- 4. **Conduct investigations of complex problems**: Use research-based knowledge and research methods including design of experiments, analysis and interpretation of data, and synthesis of the information to provide valid conclusions.
- 5. **Modern tool usage**: Create, select, and apply appropriate techniques, resources, and modern engineering and IT tools including prediction and modeling to complex engineering activities with an understanding of the limitations.
- 6. **The engineer and society**: Apply reasoning informed by the contextual knowledge to assess societal, health, safety, legal and cultural issues and the consequent responsibilities relevant to the professional engineering practice.
- 7. **Environment and sustainability**: Understand the impact of the professional engineering solutions in societal and environmental contexts, and demonstrate the knowledge of, and need for sustainable development.
- 8. **Ethics**: Apply ethical principles and commit to professional ethics and responsibilities and norms of the engineering practice.
- 9. **Individual and team work**: Function effectively as an individual, and as a member or leader in diverse teams, and in multidisciplinary settings.
- 10. **Communication**: Communicate effectively on complex engineering activities with the engineering community and with society at large, such as, being able to comprehend and write effective reports and design documentation, make effective presentations, and give and receive clear instructions.
- 11. **Project management and finance**: Demonstrate knowledge and understanding of the engineering and management principles and apply these to one's own work, as a member and leader in a team, to manage projects and in multidisciplinary environments.
- 12. **Life-long learning**: Recognize the need for, and have the preparation and ability to engage in independent and life-long learning in the broadest context of technological change.

PROGRAM SPECIFIC OUTCOMES (PSO)

PSO1: Ability to Formulate and Simulate Innovative Ideas to provide software solutions for Real-time Problems and to investigate for its future scope.

PSO2: Ability to learn and apply various methodologies for facilitating development of high quality System Software Tools and Efficient Web Design Models with a focus on performance optimization.

PSO3: Ability to inculcate the Knowledge for developing Codes and integrating hardware/software products in the domains of Big Data Analytics, Web Applications and Mobile Apps to create innovative career path and for the socially relevant issues.

COURSE OUTCOMES

	SUBJECT CODE: C213					
	COURSE OUTCOMES					
Cst204.1	Summarize and exemplify fundamental nature and characteristics of database systems					
CST204.2	Model real word scenarios given as informal descriptions, using Entity Relationship diagrams.					
CST204.3	Model and design solutions for efficiently representing and querying data using relational model					
CST204.4	Demonstrate the features of indexing and hashing in database applications.					
CST204.5	Discuss and compare the aspects of Concurrency Control and Recovery in Database systems					
CST204.6	Explain various types of NoSQL databases.					

 $Note: H-Highly\ correlated = 3, M-Medium\ correlated = 2, L-Less\ correlated = 1$

S:NO;	TOPIC	PAGE NO:
1	Information Retrieval Query languages And their brief description	155
	1	156
2	Latest tools used for ER diagram	156

Syllabus

Module 1: Introduction & Entity Relationship (ER) Model Concept & Overview of Database Management Systems (DBMS) - Characteristics of Database system, Database Users, structured, semi-structured and unstructured data. Data Models and Schema - Three Schema architecture. Database Languages, Database architectures and classification. ER model - Basic concepts, entity set & attributes, notations, Relationships and constraints, cardinality, participation, notations, weak entities, relationships of degree 3.

Module 2: Relational Model Structure of Relational Databases - Integrity Constraints, Synthesizing ER diagram to relational schema Introduction to Relational Algebra - select, project, cartesian product operations, join - Equi-join, natural join. query examples, introduction to Structured Query Language (SQL), Data Definition Language (DDL), Table definitions and operations — CREATE, DROP, ALTER, INSERT, DELETE, UPDATE.

Module 3: SQL DML (Data Manipulation Language), Physical Data Organization SQL DML (Data Manipulation Language) - SQL queries on single and multiple tables, Nested queries (correlated and non-correlated), Aggregation and grouping, Views, assertions, Triggers, SQL data types. Physical Data Organization - Review of terms: physical and logical records, blocking factor, pinned and unpinned organization. Heap files, Indexing, Singe level indices, numerical examples, Multi-level-indices, numerical examples, B-Trees & B+-Trees (structure only, algorithms not required), Extendible Hashing, Indexing on multiple keys — grid files. COMPUTER SCIENCE AND ENGINEERING

Module 4: Normalization Different anomalies in designing a database, The idea of normalization, Functional dependency, Armstrong's Axioms (proofs not required), Closures and their computation, Equivalence of Functional Dependencies (FD), Minimal Cover (proofs not required). First Normal Form (1NF), Second Normal Form (2NF), Third Normal Form (3NF), Boyce Codd Normal Form (BCNF), Lossless join and dependency preserving decomposition, Algorithms for checking Lossless Join (LJ) and Dependency Preserving (DP) properties.

Module 5: Transactions, Concurrency and Recovery, Recent Topics Transaction Processing Concepts - overview of concurrency control, Transaction Model, Significance of concurrency Control & Recovery, Transaction States, System Log, Desirable Properties of transactions. Serial schedules, Concurrent and Serializable Schedules, Conflict equivalence and conflict serializability, Recoverable and cascade-less schedules, Locking, Two-phase locking and its variations. Log-based recovery, Deferred database modification, check-pointing. Introduction to NoSQL Databases, Main characteristics of Key-value DB (examples from: Redis), Document DB (examples from: MongoDB) Main characteristics of Column - Family DB (examples from: Cassandra) and Graph DB (examples from: ArangoDB)

MODULE NOTES & QUESTION BANK

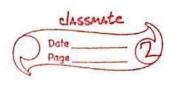

MODULE I Q:NO: **QUESTIONS** CO KL **PAGE** NO: CO1 K5 Define Database Management System. Describe Data Independence? CO1 2 K2 14 3 Discuss the main characteristics of the database approach and CO1 K2 19 how it differs from traditional file systems? Explain different Database users. CO1 K4 22 4 List the responsibilities of DBA. CO1 25 5 K2 Explain different types of attributes. CO₁ K2 58 6 Define Entity Relationship design Issues. CO₁ K5 18 Describe Weak Entity set with Example. 8 CO1 K5 39 **MODULE II** CO2 1 **K**2 46 Write a sample statement in DML and in DDL. 2 CO2 K4 42 Explain different steps in mapping E R Diagram into Relational Schema with Example. CO2 K2 3 44 Define the following terms: a) Super key: 4 CO2 K2 44 Define Candidate Key 5 CO2 K2 44 Define Primary Key Explain Integrity Constraints. CO2 K3 56 6 What are different Relational Algebra Operations CO₂ K5 62 **MODULE III** CO3 K2 1 82 Define Assertion in SQL with example. 2 CO3 K3 85 Describe View Materialization? 3 Illustrate group by clause with the help of example CO3 K4 71 CO3 K5 4 76 Differentiate having and where in SQL with example.

5	Consider the following database with primary keys underlined	CO3	K5	71
	Suppliers(<u>sid</u> , sname, address)			
	Parts(<u>pid</u> , pname, color)			
	Catalog(<u>sid,pid</u> , cost)			
	Write SQL queries for the following:			
	i. Find the names of suppliers who supply red			
	part.			
	ii. Find the names of suppliers who supply red			
	part or green part.			
	iii. Find the names of suppliers who supply red			
	part and green part.			
	iv. Find the names of supplier who supplies parts			
	of maximum cost with part name.			
6	Consider the following database with primary keys underlined	I CO3	K5	71
	Course (Courseid, CName, Credits)			
	Student (<u>Roll No</u> , Name, Gender, Address, Advisor)			
	Professor(<u>Profld</u> , PName, Phone)			
	Enrollment(RollNo,Courseld,Grade)			
	Write SQL statements for the following:			
	i. Names of female students			
	ii. Names of male students with advisor name			
	RollNo & Name of students who have not enrolled for any			
	course.			
	MODULE IV			
1	Define Functional Dependancy.	CO4	K2	90
2	Discuss different anomalies in database design with examples	. CO4	K1	87

3	Describe Armstrong's Axioms.	CO4	K3	88
4	Define Minimal Cover	CO4	K2	92
5	Explain Normalization	CO4	K5	88
6	Define Lossless decomposition	CO4	K2	98
7	Differentiate between 3NF and BCNF with proper examples.	CO4	К3	92
8	Discuss Functional Dependancy.	CO4	К3	85
9	Discuss different anomalies in database design with examples.	CO4	K2	86
10	Explain the Algorithm for lossless decomposition.	CO4	K4	102
11	Compare different Normal Forms	CO4	K4	90
12	Justify the role of Normalization	CO4	K5	86
	MODULE V			
1	With neat diagram explain Transaction states.	CO5	K4	
2			17.7	130
3	Write short notes on ACID properties.	CO5	K2	130
	Write short notes on ACID properties. Briefly explain System Logs.	CO5		
4			K2	132
	Briefly explain System Logs.	CO5	K2 K3	132 137
4	Briefly explain System Logs. Investigate in detail about transaction schedule.	CO5	K2 K3	132 137 128
4 5	Briefly explain System Logs. Investigate in detail about transaction schedule. Explain in detail about two phase locking.	CO5 CO5	K2 K3 K2 K2	132 137 128 139

* Data

Data means known facts that can be recorded & have implicit meaning. For eg: names, telephone nos & adelesses of the people.

Data can be classified into

> Structured data

> Somistauchused data

> Unstauchused data.

-> Structured Data: refers to any data that resides in a fixed field within a record or file. This includes data contained in relational databases & spreadsheets. Data has been organised into a formatted repository, a database, so that its elmts can be made addressable for more effective processing & amalysis. A data structure is a kind of repository that organizes inf for that purpose. In a database, each field is discrete & its inf can be retrieved either separately or along with data from other fields, in a variety of combinations.

-> Semi-structured Data: is a form of structure data that doesn't conform with the formal structure of data models associated with relational dbs or other forms of deata tables. It is self describing structure. It has not been organized into a specialised repository, such as db, -> Unstructured Data: is information that either doesn't have a pre-defined data model or is not organized in a pre-defined manner. Unstructured info is text heavy, but may contain deata such as dates, no s q faits as well. This results in irregularities q ambigutes that make it difficult to understorned.

Example: A word document is generally considered to be constructured data. We can add metadata tags in the form of keywords & other metadata that represent the document cont. & make it easier for that document to be found when people search for those terms - the data is now semi structured. The doct document is converted into complex orgn of db, it is fully structured data.

Comparison:

Structured 8/ms are those where the activity of processing & old is predetermined & highly organized.

ATM transactions, airline reservations etc are all forms of structured s/ms.

Chstructured data are that have no predeter form or structure. Eg: Email, reports, contracts etc.

Concept & Overview of DBMS:

* Database: is a collection of related data.

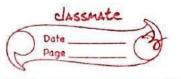

Properties of Database:

1. represents some aspects of real world-It is called the universe of discourse (VoD). Changes to this are reflected in db.

2. a logically coherent coll of data with some inherent meaning.

3. It is clesigned, built & populated with data for a specific purpose. It has intended users.

Eg: Amazon, large + commercial db.

* Database Management System: is a collection of pgms that enables users to create & maintain a database. It faultitates the processes of defining, constructing, manipulating & sharing db among vaerous users & apples. - Defining a db involves speufying the data types, structures & constraints of the data to be stored in the database. - Meta data: The db definition or descriptive inf" is also stored in the db in the form of a db catalog or dichonary. - Constructing the db is the process of storing the data on some storage medicum that is ctalled by the DBMS. - Manipulating a db includes functions such as querying the db to setsiene specific data, updating the db to reflect changes & generating reports. Shaving a db allows multiple users & pgms to access the db simultaneously. / Pgmes Db 8/m Appli Pyms/Queics S/w to process Queries/ pgms DBMS to access stored Data Shored db Stored Db Definition Metadata

Characteristics of Database Approach:

* traditional -Pile Processing

* > Self- Dascerbing Noture of a Database 3/m.

*-> Insulation blu pgms & data, & data abstraction.

+-> Support of multiple views of Dala.

* -> Sharing of data & multiuser trans processing.

* -> Self Describing Natures of a Database 3/m:

The Database 8/m contains not only the dho itself, but also a complete dof' or description of the db structure & constraints. The inf' stored in catalog is called meta-data, & it describes the structure of the primary db.

In traditional file processing, data def" is past of the appl" pgms themselfives. These pgms are constrained to work with only one specific db, where structure is declared in the appl" pgms. Eg: an appl" pgm written in C++ may have struct or class declared +> Insulation blw Pgms & Data and Data Abstraction

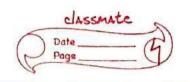

In traditional file processing, the structure of data files is embedded in the apple pgms, so any change to the structure of a file may require changing all pgm that access that file.

The structure of data files is stored in the catalog separately from the access pgms. This property is called pgm-data independence.

In object-oriented & object-relational s/ms, users can define op's on data as past of the db def's. An opn is specified in 2 parts; The iff of an op' includes the op' name & the data types of its ags.

The implementation (method) of the op' is specified separately

& can be changed without affecting the its.

User appl" pgms can operate on the data by invoking these op"s

through their names & args; regardless how the op"s are
implemented. This is called pgm-op" independance.

The characteristic that allows pgm-data independence
& pgm-op" independence is called data abstraction.

* -> Support of Multiple Views of the Data:

- Users may sequise a diff. perspective or view of the db. A view may be a subset of the db or it may contain vistual data that is derived from the db files but is not explicitly stored. Some users may not need to be aware of whether the data they sefer to 13 stored/derived.

* Sharing of Data & Mulhiuser Transaction Processing:

- A multiuser DBMS, must allow multiple users to access the db at the same time. The DBMS must include concurrincy cts/ s/w to ensure that several users trying to update the same data so that the results of updates is correct.

Eg: Aisticket reservation 3/m: updation of seat availability. Such applications are called Online Frams? Processing (OLTP).

Advantages of using a DBMS * Controlling Redundancy:

in different the places. Problems due to Redundancy are

1. Consider student data record. Entering data on a new student; there is a need to perform a single logical update multiple times. Once for each file where student data is recorded.

2. Stored Storage space is wasted when same cluta is stored repeatedly.

3. Inconsistent data - when an update is applied to some of the files but not to others.

* Restricting Unauthorized Access:

DBMS provides a security & authorization subs/m which DBA uses to create accounts & to specify account restin * Providing Persistent Storage for Program Objects & Data Struck Dalabases can be used to provide persistent storage for pgm ohds & data structures. The values of pgm variable are discarded once a pgm terminates. The pgmmer explicitly stores them in permanent files. An objet is said to be persisten since it survives the termination of pgm exc & can later be directly setriened by another pgm. * Permitting Inferencing and Actions using Rules:

- Defines deduction rules for inferencing new inf from the stored db facts. Such slms are called deductive db.

* Providing Multiple User Interfaces:

DBMS provide a variety of cases interfaces. Query languages for casual users; pgmming lang. iff for appli pgmmess; forms & emd codes for parametric users; & Menu driven iff & natural long. YFs for stand alone uses. * Representing Complex Relationships Among Data:

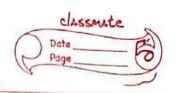

A db may include numerous various of date that are interrelated in many ways. DBMS must have the capability to represent variety of complex relations among the data as well as to returne Eupdale related data easily & efficiently.

* Enforcing Integrity Constraints:

Most do applications have integrity constraints that must hold for the data. DBMs should provide capabilities for defining & emporcing these constraints. Eg: specifying a data type for each data 16m. Name - chae:

* Providing Back up & Recovery:

BBMS provide faulties for recovering from how or Blw failures. The Back up or Recovery s/m is responsible for

* Database Administrators:

In any org?; where many persons use the same resources, there is a need for a chief administrator to oversee & manage these resources. Here the primary resource is the db itself & secondary resource is the DBMS & related slw. The DBA is responsible for authorizing access to the all for coordinating & monitoring its use; & for acquiring slw & how resources as needed. And also DBA is accountable for phlms such as breach of security or poor slm response hime.

* Database Users:

Database Designers: one responsible for identifying the data to be stored in the db & for choosing appropriate structures to represent & store this data. They communicate with all productabase users, in order to understand their regrets & to come up with a design that meets there regrets.

-> End Users: are the people use jobs require access to the db for querying, updating & generating reports.

Several Categories of Endrusces:

+ Casual end users: occasionally access the db; but they may need diff. inf " each time. They use db query lang. to specify their rests.

* Naive or parametric enclusers: revolves around constantly querying & updating the alb using stal types of queries Eupdates. called canned transps. The tasks are:

Bank tellers check account balances & post withohowalse deposits.

Reservation clerks for hotels, aixlines et a check availability for a given egst & make reservations.

* Sophisticated end users: engrs. scientists, business analysts of others who thoroughly familiarize themselves with the faulities of the DBMS so as to implement their apples to meet their complex sqmits.

* Stand alone users: maintain personal olds by using ready made pgm packages that provide easy to use min or graphics based ifs.

System Analysts: abtermine egmnts of end weeks & develop specific's for canned trans's that meet these egmnts Appl' pammers: implement these specific's as pams; thus they test, dobug , clocument & maintain canned trans's.

* Data Models:

A data model is a collection of concepts that can be used to describe the structure of db. The concepts and data types, relationships, constrounts & basic op's for specifying retrievals & updates on the db.

-insert, delete, modely or retrieve are basic data

model opis.

Categories of Data Models:

High level/Conceptual data models: concepts that are close to the way many users percione data.

Low level/physical data models: concepts that describe the

details of how dela is stored in a computer.

Representational/Implementation data models: concepts that may be understood by end users & the way data is organism within the computer.

Conceptual data models use concepts such as

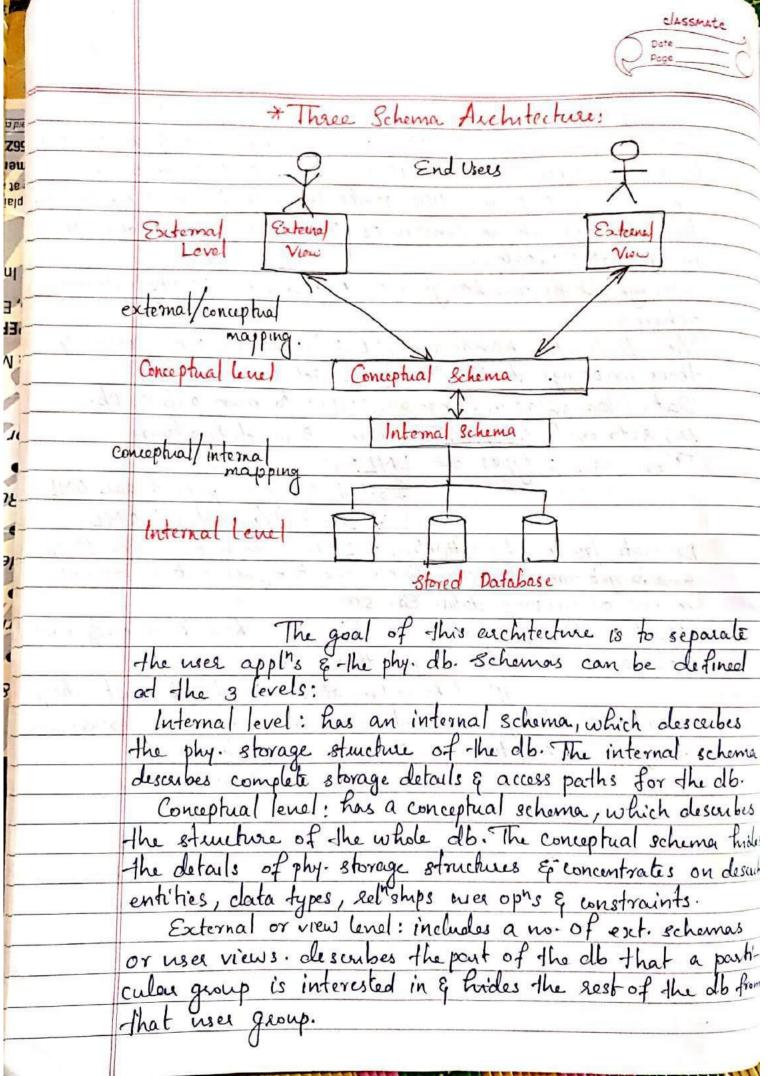

entry, attendates & reliships.

An entity sepersents real world obje or concept such as employee or a project. An attribute sepresents some property of entity eg: 10. Relationship sepresents interactions among entities.

Schemas: The elescription of db. which is specified during db design. Theme Is North Class Many

Instances: The data in the old at a particular moment in time is called database state or sneepshot.

	Database Languages:
	a land land land of DBA & GO CONTINUES

-	- Cont Date Comp.

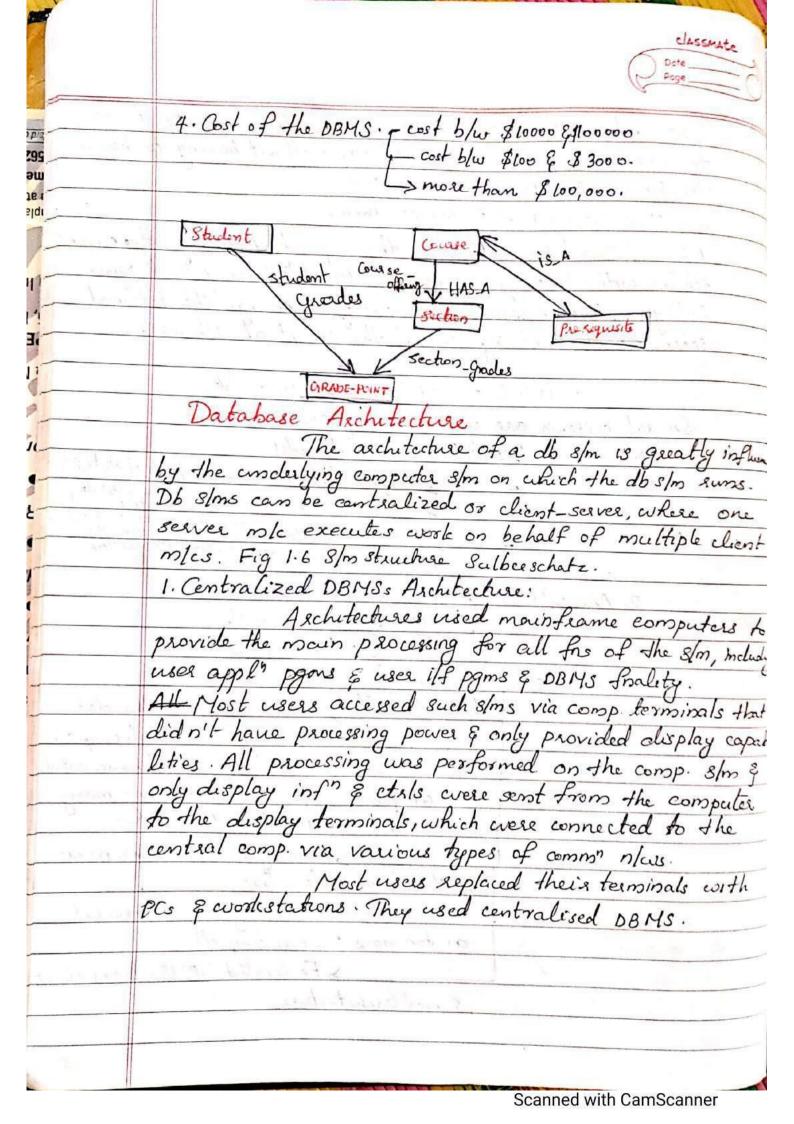

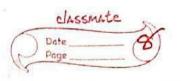

Data Independance: can be defined as the corporery to change the schema at one level of a db slm without having to change the schema at the next higher lend. Two types of clata Independence; schema wothout having to change external schema or apple pgms. 2. Physical Data Independence: corpacity to change the internal schema without having change the conceptual schemas. * Classification of Database Ugmt 8/ms: Several criteria are used to classify DBMS. 1. Data mode/ports based relational model > Object data mode/-db inferms of objts, propor > Objt solational model-ROBMS with objt of &

Street structures, each housely

Historical Model and of related records.

N/w model-2. No. of users supported by the s/m > Single uses 8/m > Mulhiuses 8/m 3. No. of sites over which Ob is distributed > centralised - if the data is stored at a single comp site. > Distributed - can have actual db & DBMS 8/w distributed over many sites connected by a comp. n/w. > Homogeneous - same DBMS Slwat multiple sites. > Heterogeneous-several autonomous pre existing db. > Feclerated DBMS - uses client Serves architecture.

Lient/Server Aschitectures.

— deal cirth computing envis in which a large no of Pls, workstations, file servers, printers, db servers, web servers of other equipment are connected via a n/w. The i'dea is to define specialized servers with specific finalities. For eg: it is possible to connect a no of Pls or small workstations as elsents to a file server that maintains the files of the dient mes. Another m/c could be designated as a printer server by being connected to various printers; thereafter, all print rysts by the clients are forwarded to this m/c. The client mts provide the user with the appropriate 1/fs to utilize these servers, and with local processing power to sum local appl's.

Pant File DBYS
Server Server

The client/server framework consists of many PCs & workstations & smaller no of mainframe m/cs connected via LAN or other comp. n/ws.

A client is a cise m/c that provides uses iff capablitus & local processing. When a client requires access to address finality—such as db access—that cloesn't exist at that m/c, it connects to a server that provides the needed finality.

A server is a m/c that can provide services to the client m/cs such as file access, printing, archiving or abaccess. Bome m/cs install only client s/w others only server s/w; & others may include both client & server s/w. Two main types of DBMs architectures — two-tier

three-ties.

* Entity Relational Model

-> Database Application

-> Conception programs.

-> Phower of db design.

Fig : 3.1

> Basic Concepts

A db application can be displayed by means of the graphical notation known as E-R diagrams.

Example Company Database Application.

Fig 3.2.

* Entities & Attributes:

Entity is a basic objt which is a thing in the seal world with an independent existence. Its an objt with a physical existence eg: person, car, house or employee. Each entity has attubutes, particular properties that desurbed by name, age, adde. Esday A particular entity will have a value for each of its attubuted several types of attubutes:

1. Simple versus Composité Affaibutes:

Attributes that are not divisible are called Simple or atomic attributes. Composite attributes can be divised into smaller subparts, which represents more basic attribute with independent meanings. For eg: the Address attribute can be subdivided into street Address, City, State & Zip. with diff. values. Street Address can be subdivided into 3 simple attributes, Number, street & Apartment No.

Street Address City State Zip

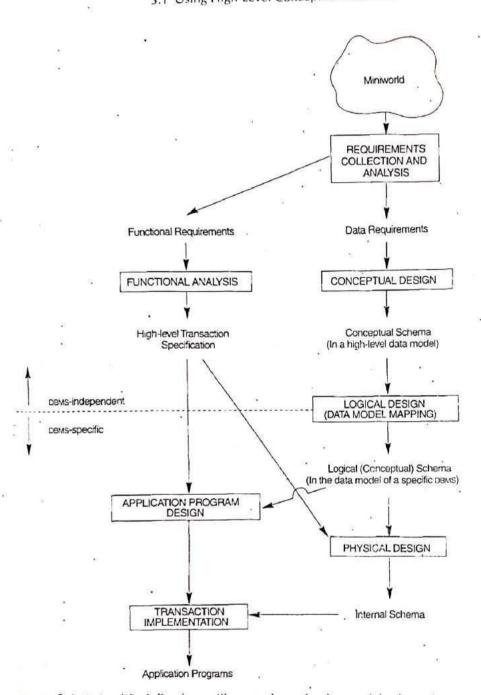

FIGURE 3.1 A simplified diagram to illustrate the main phases of database design.

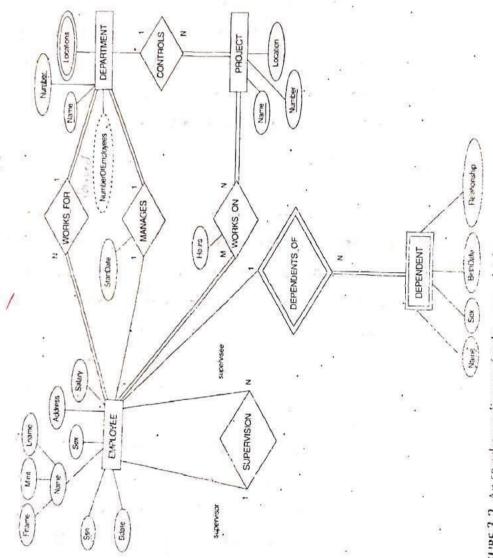

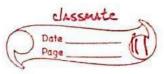

FIGURE 3.2 An ER schema diagram for the cornaw database,

	2. Single-valued Versus Multivalued Attaibutes:
	Attributes that have a single value for a particulus
	entity called single-valued attributes. Eg: Age.
4	Attributes - that have a set of values for the
	same entry called multivalved attendutes. Eg: College Degrees, Phone
	3. Stored versons Derined Affeibules:
	The attendite that can be desired from es
	other afterbutes, called desired afterbute. The attribute from
	which it is derined is called stored Attenbuli.
	Eg: Age can be derived from Date of Birth.
,	Iderined attribute stored Afterbute.
	4- Null Values:
I	A particular entity may not have an applicable value
	for an attubute eg: Apartment No of an address applies only to
1774	addresses that are in apartment buildings. (Not Applicable)
	Null can also be used if we do not know the value of at attain
	but for a particular entry - eg: home phone of "Smrth".
	5. Complex Attabutes:
	Composite & multivalued attributes can be nested in an
-	ashitrary way. &: [Address Phone (Phone (Asea Gode, PhNa),
	Address (Street Address (Number, Street, Apast. No) City, State, Zip) .
اس	Entity Types, Entity Sets, Keys & Value Sets:
	An entities An entity type defines a collection of
	entities that have the same attendutes. Each entity type in the
	db is described by its name & attributes. Entities share the same
	attendets, but each entry has its own value for each attendet
-	Entry Type Name: Employee Company Nome, Heuseles, President
	21.
	Entity set: TSmith, SE, 80k (Sunco 01/ John Smith)
	Extension (Fruly, 40, 30K) (Fast, Dallay, Bob)
	e3.
	(Judy, 25, 20k)

An entity type is represented in ER diagrams as a see sectangular bose enclosing the entity type name. Attach names are enclosed in ovals & are attached to their entitype by straight lines. Composite attenbulis attached to the component attubutes by straight lines. Multivalued attribute are displayed in double ovals.

type in the db at any pt. in time is called an entry set.

Also called extension of the entity type.

Key Attributes of an Entity Type:

An entity type usually has an altribute whose values are distinct for each individual entity in the coll. Such as an attribute is called a key attribute of its values can be used to identify each entity uniquely. For eg: the Name aftribute is a key of the Company entity type b/c no two companies are allowed to have the same name.

For the Person entry type key attribute is SSN.

Several attributes together form a key, meaning that the comb" of the attribute values must be distinct for each entity. If a set of attributes possesses this property its. composite attribute that becomes a key attribute of the entity type. In ER, diagram, each key attribute has its name emplestined inside the oval.

Value Sets (Domains) of Attributes:

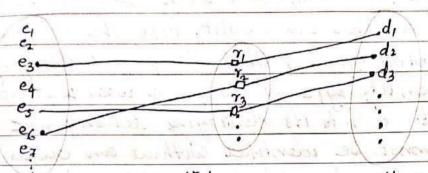

Each simple attribute of an entity type is associated with a value set (domain of values), which specifies the set of values that may be assigned to that attribute for each individual entity. Eg: The value set for Name attribute as being set of strings of alphabetic characters separated by blank characters & so on. Value sets are not displayed in ER diagrams.

Relationships, Relationship Types, Riles & Structural Constraints. Relationships: an attribute of one entity type refers to another entry type; Eg: The attribute Manager of Department refers to an employee who manages the dept. Relationship Types: A relationship type R among n' entry types E, Ez -- En defines a set of associations-or a seliship selamong enthies from these types. Relationship instance Di in Ris an association of entities, where association includes exactly one entry from each participating entity type. For eg: a relationship type works-for blu the Department entity. Relationship Degree; is the no of participating entity types. Eg: the works-for relationship is of degree hus. A relationship type of degree two is called binary & one of degree three is called ternary. Employee Department. Helatronships as Atherbatase Role Names: The sole name signifies the sole that a participating entity from the entity type plays in each selling instance, & helps to explain what the sel ship means Eg: Employée plays the sole of employee & Department plays The role of dept. or employer Recussive Relationships: In some causes the same entry type participates more than once in a reliship type in

diff. xolos. In such cases the xole name becomes essential for distinguishing the meaning of each packicipakon. But rel'ship types are called recuesine relationships. Eg: The supervision reliship type relates an employee to a supervisor where both employee & supervisor entite are members of same Employee entry type. Constraints on Relationship Types: Rapos of Relationship types have certain constraints that limit the possible comb's of antithes that may participate in the coises. sel'ship set. For eq! in the works for selling type, Employee plays the sole of employee or worker & Department plays the sole of department or employer. There are two main types of relationship constraints: > pashicipation. Cardinality Ratios for Binary Relationships: The caldinality rate for a binary retiting specifies the no of relithip instances that an entry can pasticipate in. For eg:, in the wooks for binary rets. type, Department: Employee is of cardinality ratio 1:N, 10; each dept can be related to (10; employs) no. of employed but an employee can be related to (work for) only one dight The cardinality latios for binary seliship types an 1:1, 1:N, N:1 & M:N. An eg. of a 1:1 binary reliship is MANAGE which strelates a dept entity to the employee who manages that ex dept. Participation Constraint: -specifies whether the existence of an entry depends on its being related to another entity via the ReMship. type. There are a types of participation constraints--total & partial.

Egilfa company policy states that every employee must work for a dept, then an employee entity comexist only if it participates in a curios-for reliship instance. Thus, the participation of Employee in works-for is called total participation => every entity in "the total set" of employee entities must be related to a dept. entity via works for. Total participation is also called exestence depending.

1:1 reliship manages with partial participation.

of employee & total participation of Department.

Eg: we do not expect every employee to manage a dept,

80 the participation of employee in the (manages) reliship

type is partial, mad meaning that some or part of

the set of employee entities are related to a dept.

entity via manages, but not necessarily all.

Cardinality ratio & pashispation constraints together is called structural constraints.

In ER diagrams, total participation as a double line connecting participating entity type to the Relationship Types:

Attributes of Relationship Types:

Relationship types can have attendutes. For eg: to second no. hours/week that an employee works on a pasticular project, we can include an attendute Hours for the works-on relationship type.

* Weak Entry Types:

נק כו

Entity types that do not have key attended of their own are called weak entity types. Régular entit types that do have a key attended are called strong entity types.

Entities belonging to a weak entry type are identified by being related to specific entities from and entry type in combination with some of their attentive values. We call this other entry type the identifying or owner entry type. & the reliship is identifying relish. A weak entity type always has a total participation constraint wire to its identifying reliship ble weak entity cannot be identified without an owner entry.

which is the set of attenbulis that can conquely identify weak entities that are related the same owner entity

In ER diagrams, both a weak entity type & its identifying sel'ship are sepresented by some rules their boxes & diamonds with double lines. The partial key is underlined with dashed or dotted line.

* Relationship types of Digree greater Than Two:

Relationship type of degree 2 binary & a reliship type of degree 3 ternary.

-> Choosing blw Binary & Ternary (or Higher-Degree)
Relationships:

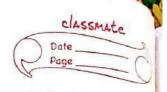

A Rel'ship type R of degree n will have nedges in an ER diagram, one connecting R to each participating entity type. Fig(a) displays the scheme for the supply sel'ship type.

Fig(b) shows an ER diagram for the three binary Rel'ship types CAN_SUPPLY, USES, and SUPPLIES.

Scanned with CamScanner

A terrary relishiptype represents more info than do three binary reliship types. Fig (c) The 3 participating entity types SUPPLIER, PART & PROJECT are logether the owner entity types. An entity in the weak entity type SUPPLY of fig is identified by the combo of its three owner entities from SUPPLIER, PART & PROJECT. -> Constraints on Ternary Co. Higher-Degree) Relationships: There are two notations for specifying struction ral constraints on n-acy relationships, & they specify diff. constraints. They should thus both be used if it is important to fully specify the structural constraints on a dernacy or higher degree reliship. (CName Name Coundidate CCI Company Date Interview Job offer pry-amout Com E-R Dragram with a weak entity set.

Entry-Relationship Design Issus:

The notions of an entity set & a reliship set are not precise, & it is possible to define a set of etities; the reliships among them in a no. of deff. ways.

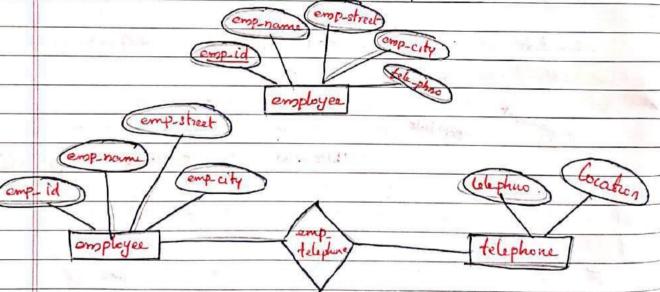

Basic Issues are:

1. Use of Entity Sets versus Attributes:

Consider the entry set employee with attention emp-id, emp-name & tele-phno. Telephone can be an entry with attentites tele-phno & location (office, home, mobile --). Realefine the employee entry set as

* The employee entity set with attributes empid genprim
* The telephone entity set with attributes tele-phono & lock.

* The Rel'ship set emp_telephone, denoting the association blue employees & the telephones that they have.

Treating a telephone as an attribute telephno implies that employees have precisely one telephno. each. Treating a telephone as an entity telephone premits employees to have seneral feliphnos. associated with them. Instead, define telephone as a multivalued attribute to allow multiple telephones per employ.

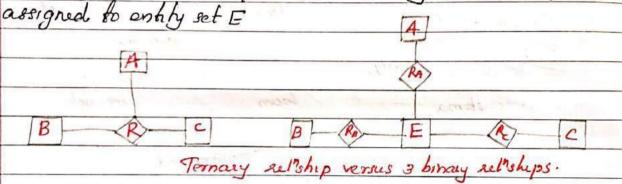

The main diff. is that treating a telephone as in entity better models a situation where one may want to be extra info about a telephone such as its loch or its type

or all who share the telephone The distinctions blw afterbute & entity set depend on the structure of the real world enterprise being modeled & on the semantics associated with the attenbule. 2. Use of Entity Sets versus Relationship Sets: -> It is not always clear whether an objt is bet expressed by an entity set or a relationship set. For eg: a bank loan is modeled as an entity. An alternative is to model a loan not as an entity, but rather as a relitip blu customers & beanches with los & amount as descriptive attributes. (cus-name) cus-street be same cus id branch Locun customer We cannot represent a situation in which several customers hold jointly. To handle such a situation, we must define a separate reliship for each holder of the joint loan. Then we must replicate the values for the descriptive attributes and & amount in each such reliship. Each such seliship must have same value for the attributes I no & amount. Two plans arise as a result of the replication: (1) the data are stored multiple times, wasting storage space (2) applates potentially bane the data in an inconsistent state, where the values differ in two selships for attributes that are supposed to have the same value. 3. Binary versus n-ary Relationship Sets! That appear to be non binary could actually be represented by seneral bibasy sellships.

For eg: one could create a ternary relishup parent, relating a child to his/her mother & father. Such a retiship would be represented by two binary retiships, mother & father, relating a child to his their mother & father separately. Consider the beinasy sel'ship set R, Relating entity et A, B, & C. Replace the Relatiship set R by an entity set E, & create 3 & reliship sets * RA, relating E & A * RB, relating E & B

* Rc relating E&C.

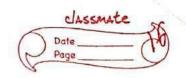

If the sel'ship set R had any attributes, these are

The restriction to include only binary relationship set is not always desirable.

4) Placement of Relationship Attenbates:

The cardinality ratio of a reliship can affect the placement of reliship attributes. Attendutes of one-to-on or one-to-many sel'ship sets can be associated with one of the participating entity sets, rather than with the retrohip set. Fox eg: Depositor is a one to many relishipet such that one customer may have several accounts, but each account is held by only one customer. In this case, the attribute access-date, which specifies when the customin last accessed that account, could be associated with the account entity set. Since each account entity perticipates in a seliship with at most one instance of customer, making This attentite designation would have the same meaning

as would placing access-date with the depositor reliship set.

Attributes of one to many reliship set can be repositioned to only the entity set on the "many" side of the reliship. For one-to. one reliship sets, the reliship attribute can be associated with either one of the participating entities.

The disign decision of where to place descriptione attributes a in such cases - as a reliship or entity attribute - should reflect the characteristics of the enterprise being modeled. The designer may choose to retain access date as an attribute of depositor to express explicitly that an access occurs at the pl. of interaction blu the customer & account entity sets.

Keys - Constraints.

Entities within a given entity set are be distinguished. The values of the attribute values of amenty must be such that they can uniquely identify the entity. A key allows the to identify a set of attributes to distinguish entities from each other. Keys also help uniquely identify relationship, & distinguish reliships from each other.

1. Entity Sets:

A superkey is a set of one or more attendity allow to identify uniquely an entity in the entity set. For eg! the cus-ide attended is sufficient to identify uniquely an entity in the entity set.

For eg: the cus-id attribute of the entity set customer 13 sufficient to distinguish one customer entity from another Thus ous-id is a superkey. The combination of cus-rame ; cus.id is a superkey for the entity set customer. The cus. rem. attribute of customer is not a superkey, ble several people night have same name.

If K is a superkey, then so is any supersel of K. Minimal superkeys are called comdidate keys. A combo of cus-name and cus-street is sufficient to disting among members of the customer entry set. Both Ecus. id & {cus-name, cus-street} are condidate keys. Although the attributes cus-id & cus-name together can distinguish austin entities, their combo doesn't form a candidate key, since

the attendute cus id alone is a candidate key. - Primary key to denote a coundidate key that is chosen by the db designer as the means of identifying entities within an entity set.

- A key (primary, candidate & super) is a peoperty of the entity set, sather than of individual entities. -Primary key should be chosen such that its

attributes are never, or very sevely changed.

2. Relationship Sets:

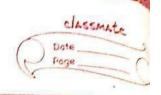

- mechanism to distinguish among the various selbups of a relibility set. The composition of the primary key for a reliship set depends on the set of attenbutes associated with the reliship set R. If the relished set depends on the set of attributes associated with it, then the set of attubutes

primary-key (E,) U primary-key (E2) U -- - primary descubes an individual sel'ship in set R.

If the reliship set R has attendates a, az--am association with it, then the set of attabutes

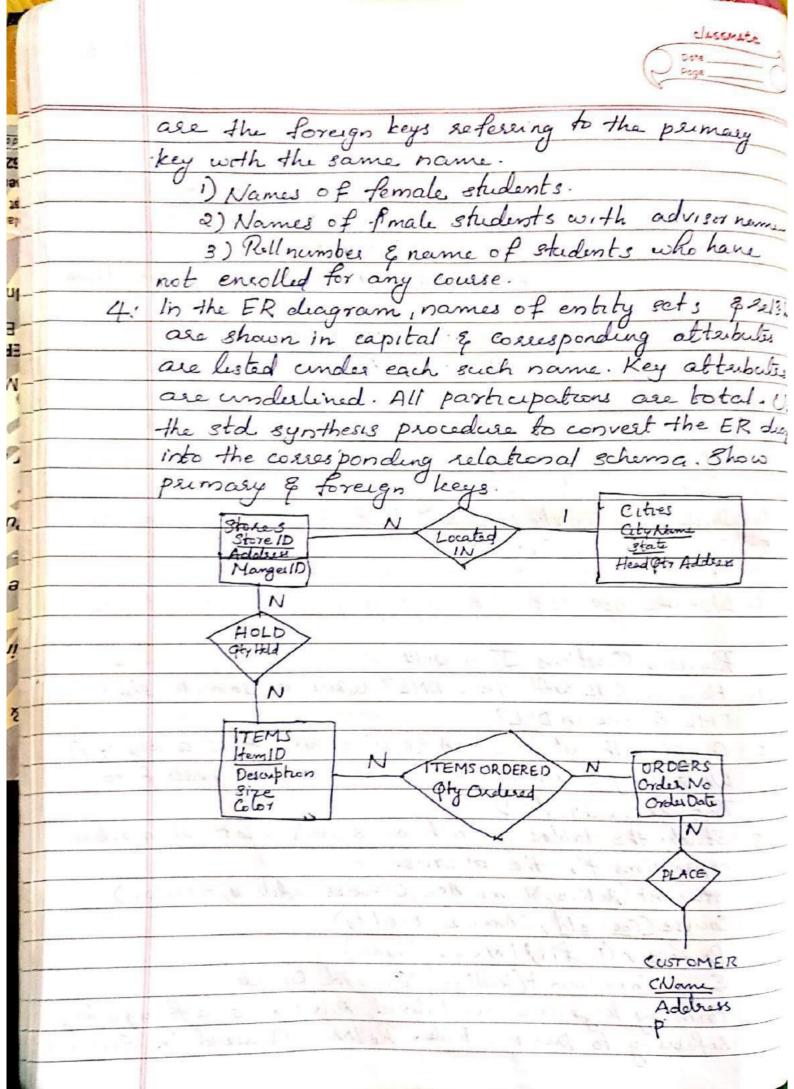

primary-key(E1)U primary-key(E2)U---U primary key(En)U describes an individual relaship in set R. In both of the abone cases, the set of attendutes primary-key (E,) U primary-key (E2) U-.. Uprimary-key (En). forms a superkey for the reliship set. The staucture of the primary key for the relinip set depends on the mapping cardibality of the reliship set. Consider the entity sets customer and account, and the reliship set depositor, with attendute access date. Suppose that the reliship set is many to many. Then the primary key of depositor consists of the union of the primary keys of customes & account. If a customer can have only one account - 12; If the depositor relationship is many to one from customes to account - then the principle key of depositor is primary key of customes. If the reliship is many to one from account then the primary key of depositor is primary key of account For one to one relationships either primary key combe used. what one the Responsibilities of the DBA Define the following terms: i) Data made! ii) Itatabase schema iii) Meta what are diff ways of classifying a 1911s Explain the follow terms. iii) Covering Constraint 5. 	1-11-1			- :		

A sel is a set of tuples, we use notation of ter to denote that tuple t is in sel' ?. -> The order in which tuples appear in ralation is irrelevant, since a sel is a set of tuples. -> For all rel's or, the domains of all attendutes of o be atomic. A domain is atomic if elmts of the domain are considered to be indivisible anits. Fox eg: the set of integers is an atomic domain, but the set of all sets of integers is a nonatomic domain. -> Several attributes have the same domain. For eg: a relation customer that has 3 attenbutes cus-name, cus-street & cus-city & a sel employee that includes the attenbute Ename. The attenbutes Cus-name & Ename will the have the same domay -> One domain value that is a member of any possible domain is the null value, which signifies that the value is unknown or doesn't exist. For eg: the attribute telephno in the customer sell, a customer doesn't have a telephno or the telephno is unslisted. * Database Schema: -logical design of the db where db instance is a snapshot of the data in the db at a given instant in time. Eg: Account_schema = (AccNo, Brame, Balance) We denote the fact that account is a sell on Account Schema by account (Account schema) A sel' instance coires. to to value of a variable The value of a given variable may change with him; the conts. of a sel instance may change with time as the sel is updated. Branch. schema = (Brame, Daily, assets)

The values of the attenbute values of a tuple must be

such that they can uniquely identify the tuple.

A superkey is a set of one or more attributes that allow to identify uniquely a suple in the relation For eg:, the cus-id attribute of the rel" customer is sufficient to distinguish one customer huple from another. Illy, Comb" of cus-name & cus-id is a superkey for the rel" customer. The cus-name is not a superkey b/c several people might have the same name.

Superkey may contain extraneous attributes.

If K is a superkey, then so is any superset of K. Minimal

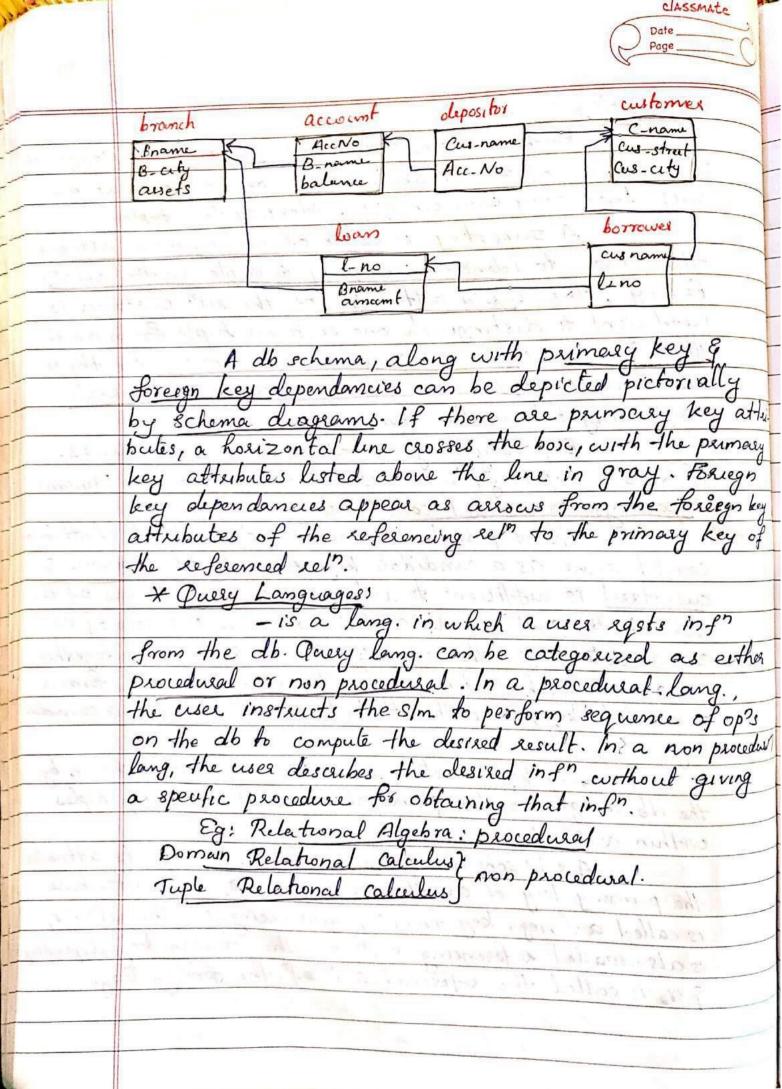

superkeys are called condidate keys.

It is possible that several distinct set of attribute could seeve as a candidate key. A comb" of cus-name & cus-street is sufficient to distinguish among members of the set". Both cust {cus-id} and {cus-name, cus-street} are candidate keys. The attributes Cus-id & cus-name together can distinguish customer tuples, their comb" doesn't form a candidate key, since the attribute cus-id alone is a combible key.

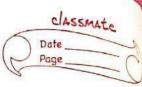

Permary key denote a candidate key that is chosen by the db designer as the principal means of identifying hiples

within attelli

A sel' schema 7, may include among its attributes the primary key of another sel' schema of. This attribute is called a foriegn key from 8, seferencing 82. The sel! or, is also called referencing sell of the foriegn key depending & 1's called the referenced sell of the foreign key depending & 1's called the referenced sell of the foreign key.

* Integrity Constraints: - ensures that changes made to the db by authorized users do not result in a loss of data consistency. Eg: An account balance comnot be null. - no & accounts can have the same all no. - Every account no in the depositor sell must have a matching account no in the account sell. - The housely salary of a bank employer must be attent \$6.00 an hour. -> Constraints on Single Relation: - Primary key constraint - Key constraints & entry integrity constraints are spenfied on individual rel's. *not null / * UNITQUE * Check((predicate)) -NOT NULL Constraint: - null value is a member of all domains & 18 a logal value for every attribute. For certain attributes, null values may be inappropriate. Consider a hiple in the account sell where Acc-no is null. Such a hyple gives account inft for an unknown account. - The not null spenfich prohibits the insest of a null value for this attribute. UNIQUE Constraint: The amque spent" says that attributes Aji, AJ, , ... Ajm form a candidate key; se; I no two typles in the rel can be on all the primary key attributes. The CHECK Clause: can be applied to sel' declarations as well as to domein declarations. Clause check(P) spenties a predicate P that must be satisfied by every tuple in a sel.

For eg:, a clause check (assets)=0) in the create take and for sel branch would ensure that the value assets is nonnegative. Key constraints & entry integuty constraints constraint is spenfied blw 2 xel's & is used to tain the consistency among hiples in the 2 sel's. The referential integrity constraint states that Entity Integrity constraint states that no primary key value can be null B/c primary key value is used to identify individual tuples.

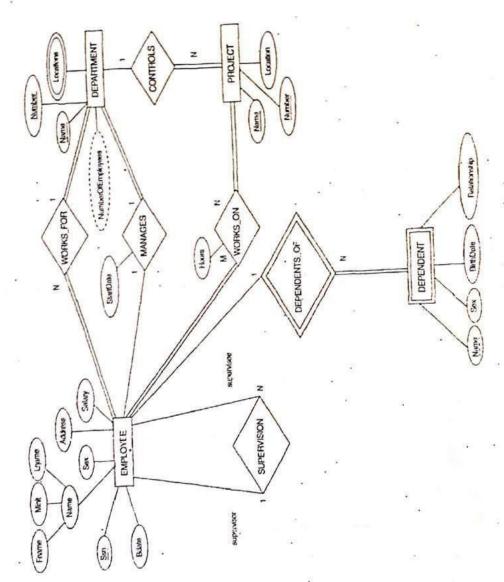

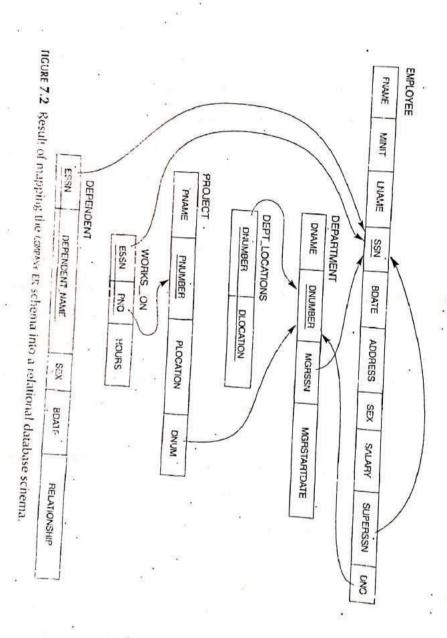

FIGURE 7.1 The ER conceptual schema diagram for the COMPANY database.

* Synthesizing E-R diagram to relational Scheme.

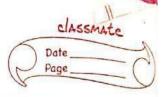

Fig 7.1 € 7.2 ⇒ Mapping Steps:

Step 1: Mapping of Regular Entity Types: Fox each Regular (Strong) entity type E in ER schema, exeate a rel" Rothat includes all the simple attributes of E: Include only simple component attributes of a composite attribute. Choose one of the key attributes of E as primary key for R. If the chosen key of E is composite, the set of simple attributes that form it will is together form the primary key of R.

In eg: create the relations Employee, Department & Project to correspond to the regular entity types Employee, Department & Project. We choose SSN, DNo & PNo as primary keys for the relations.

Step 2: Mapping of Weak Entity Types: For each weak entity type win the ER schema with owner entity type E, weat a set R & include all simple attributes (or all simple components of composite attributes) of was attributes of R. In addition, include as foresign key attributes of R the primary key attributes of the set correspond to the owner entity type (s);

In eg:, we create the rel dependent, we include primary key SSN of the Employee relation. which corresponds to the owner contity type - as a foreign key affaible of dependent, renamed it ESSAN. The primary key of the dependent rel is the combination ESSN, dependent and b/c dependent name is the partial key of dependent. Step 3: Mapping of the lil relationship: For each binary 1:1 reliship type R in the ER schema, identify the rel's S & T that correspond to the entity types participating in R.

Choose one of the 2013-8-8-7 that correspond to the in S the primary key of T. It is better to choose an entity type with total participation in R in the role of Include all the simple attributes of the 1:1 rel'ship type Ras attenbutes of S. fox eg: map 1:1 xel'ship type MANAGES by choosing - the participating entity type Department to serve in the role of 8, b/c its participation in The MANAGES relished type is total (every dept how a manager). Include the primary key of the employee sel as foreign key in the Department all & lename it MCRSSN. Also include the simple attendute Stortle of the MANACIES reliship type in the Department rel's Rename It Mg & Start Date. Step 4: Mapping of 1:N relationship types: Identify the rel's 3 that represents the participating entry type at the N-side of the reliship type include permany key of the Rel' T as foreign key in S. Include any simple attitude of the I: N eethship type as attendutes of S. For eg: map the I:N reliship types works for, controls & supervision. For works, for include the primary key DNo of Department relation as foreign key in the Employee relation & call it DNsmber. Step 5: Happing of M: N Relationship type: For each bi create a new relation s to represent R. Include primary keys of the relations to represent the participating entity types as foreign ky attendules in S. Include any simple attendules of MIN reliship type as attendules of S. We commot represent

in one of the participating sel's b/c of M:N condinately

Scanned with CamScanner

Eg: Map the M:N sel'ship type. works-on by weating the sel' works-on. Include the primary keys of Project & Employer Rel's as foreign keys in works-on & rename PNO & ESSN.

Also include an attenblete Hows in works-on to represent hows attenblete of the sel'ship type. The primary key of the works-on rel' is the comb' of the foreign key attributes & ESSN, PNOS.

Step 6: Happing of Multivalued Attributes: For each multia-lued attribute A, create a now relation R. This rel' R will include an attribute corresponding to A, plus primary key attribute k - as foreign key in R- of the rel' that represents the entity type that has A as am attribute. The primary key of R is the comb' of A & K. If multivalued attribute is composite, include its simple components.

For eg: create a sel Dept-Locations. The attribute DLocation supresents the multivalued attribute Locations of Department, while DNO-as foreign key-sepresents the primary key of the Department selation. The primary key of Dept-Locations is the combination of ¿DNO, Dlocatos A separate tuple will exist in Dept-Locations for each location that a dept has.

Step 7: Mapping of n-ary Relationship: create a new rel's to represent R. Include as foreign key attributes in S the primary keys of the rel' that represent point apating entry types. Also include as foreign key attributes in S'of the n-ary rel'ship as attributes of S.

> Database Languages. A db s/m provides a data de for lang. to sprufy
the db schema & a data - mornipulation lang. to expr alb queries & apolatis. * Data Manipulation Language: - enables users to access or manipulate data as organized by the appropriate data model. The types of access are - Reterieval of inf" stored in the db. - Insertion of new info into the db. - Deletion of info from the db. - Modefic? of inf" stored in the db. There are basically 2 types: * Procedural DMLs; require a user to spenty what data are needed & how to get those data. * Declaratine DMLs: (non procedural DMLs) require a user to spenty what data are needed without spentying how to get those data. A query is a start requesting the retrieval of inf? The portion of a DML that involves info return is called a query lang. Query lung; eg: 8QL. * Data Definition Language:
- Specify adb schema by a set of def? expressed by a special long, called a data def (ong. ODL)
We specify the storage structure & access methods used by the db s/m by a set of storts in a special type of DDL called a data storage & def'lang. The data values stored in the db must sahin certain consistency constraints. For eg: suppose the bal on an account should not fall below \$ 600. The DDL provides faulities to spenfy such constraints.

The db s/m concentrate on integrity constraints that combe tested with minimal overhead: * Domain Constraints: A domain of possible values must be associated with energy afterbute (eg: integes types, chas types date/time types). Declaring an attenbute to be of a pashicular domain acts as a constraint on the values that it can take. Domain constraints are the most elementary form of the integrity constraint # * Referential Integrity: A value that appears in one relation for a given set of attenbutes also appears for a certain set of attributes in another sell. Database modific's can cause violations of referential integrity. * Assertions: An assertion is any cond' that the db must always satisfy. Domain constraints & referential instegrity constraints are special forms of assections. For eg: "Every boan has at least one customer who maintains an account with a min. bal of \$100! must be expussed as an assestion. When an assestion is created, the 3/m tests it for validity. If the assertion is valid, then any future modefich to the all is allowed only if it doesn't cause that assertion to be violated. * Authorization: To differentiate among the users as far as the type of access they are permitted on various desta values in the db. - read authorization, apolate authorization, delete authorization The olp ow of the DDL 13 placed in the data dechonary, which contains metadata ie; data about date. along fellows in promothers

* Relational Algebra

> Relational Algebra Operations:

> unary operations _ select, project & rename > binary operations _ Union, Difference, Contracon Polt

* The Select Operation:

- selects tuples that satisfy a given predicale of is used to denote selection. The predicate appears as a subscript to o. Eg; select those tuples of the loan relation where the branch is " pridge"

Obname = "pridge" (loan)

Damount >1200 (loan)

-Allow comparisons using =, \pm /, \leq ,>, \geq in \pm _n selection predicate.

- combine several predicates into a larger predicate by using the connectives and (N), or (V) & not (7).

Thrame="perdge" 1 amount>1200 (loan).

- include compansons b/w a attributes.

Eg: Jausname = brame (loan-office)

* Project Operation:

-list values of selected attributes.

- The project op allows us to produce this rel - This op returns its arg. rel, with certain attribute left out. Since a sel is a set, any duplicate rows are eliminated.

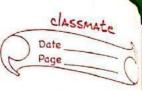

- denoted by TT. > list those attributes that we wish to appear in the result as a supscript to TT. The arg. relation follows in paranthesis.

relation follows in paranthesis

The amount (lean)

lno	amount-	1
L-11	900	t
L-14	1500	l
L-15	1500	I
L-17	1000	-
L-15	Carlo	-

* Composition of Relational Operations: Eg: Find those customers who live in Hamison". Trans (custy = "Harrison" (customer)) arg. of the projection op, we give an expression that evaluates to a sel. Since the result of a selmal algebra oph is the same type as its inputs, relational algebra ops can be composed together into relational algebra expression. Composing Relinal algebra ops into relational algebra expressions is just like composing authoretic opis (+,-, *, +) into authmetic expressions. * The Union Operation: Eg: + Find the names of all bank customers who have either an account or a loan or both. Thoustones Transma (borrows) Thus name (depositor) To answer the query, we need the union of these 2 sets, Tayname (bossower) UTTaus-name (depositor) For a umon op" TUS to be valid, we require that 2 cond's hold: 1. The sels . 2 &s must be of the same arety. le; they must have the same no of attributes. 2. The domains of the ith attribute of 8 must be the same, for all i. Cus-name Adams Cussy Hayes * The Set-Difference Operation: '- allows us to find tuples that are in one rela but are not in another. The exp. 7-8 produces a rela containing those tuples in & but not ins.

	Eg: Find all customers of the bank who have an
	Therene (de positos) - Thursname (borrower).
	Cus name
-	John
	John Lindsay
	Tunes
14.74.3 6	The set-difference opn r-s to be valid, we require
PA S	that the sel's of & s be of the same acity, & that the
1	domains of the ith attribute of & & the ith attribute
	of s be the same.
	* The Castesian - Product Operation.
ask a	- denoted by (X), allows us to combine int 100
	any two sel's, g, x 72?
	For eg: the rel's schema for 7 = borrower x Loans
	(bordowies. Cus_name, borrowes, 1-no, coan. 2-no, coan. D.
LA False	loan amount)
	They are the state of () They are called the party ()
· Am	Old A Gray hon: Program 14 PH 200
	* Set Intersection Operation: The result of this op"
my pull	denoted by Rns is a sel that includes all hiples that
	The result of the intersection opn includes only those
DE The	who are both students & instructors.
	-> UNION & INSTERSECTION are Commutative Op3.
	Rus=SuR & Rns =SnR.
	-> Associative: RU(SUT) = (RUS)UT
	: (Rns)nT = Rn(snT).
	1 The St- Defende Country
112	to the solver I had be seen to
16.1	but an not in another The up not I where
1. 3.	- containing the relies or to the

The JOIN Operation:

- denoted by M, used to combine related tuples from 2 relations into single tuples. It allows to process reliships among relations. Eg: To get the mngr's name, reed to combine each dept tuple with the employee tuple whose SSN value matches the MgrSSN value in the dept tuple.

Dept-HUR - Department MMgrssN=SSN Employee Result - TToname, Lname, Frame (Dept-Mgr)

- A general join conclution is of the form:

< condition) and (condition) and (condition) --- and

where each cond is of the form A; OB; , Ai is an abturble of R, B; is an attribute of S, Ai & B; have the same domain and Q is one of the comparison operators $\{=, <, \leq, >, >, \neq, \}$ A- Join operation with such a general cond is called a Theta Jow.

Equijoin involves join cond's with equality comparisons only. Conly = operator is used.

Natural Join: lequises that the 2 join attributes have the same name in both relations. elevated by *.

If this is not the case, a renaming op is applied first.

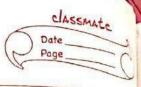

Eg: first rename the Drumber attribute of Department to Drum - 30 that it has the same name as the Drum attribute in & PROJECT - then apply Natural Join.

PROJ_DEPT RROJECT * DCDNAIME, DNUM, MURSSN, MURSTARTDATE)

(Deposet ment)

If the attendutes on which the natural join is specified have the same names in both rel's, renaming is unuserssay. For eg: to apply a natural join on the DNumber attendutes of Department & Dept-Locations

Dept-Low & Department of Dept-Locations.

	*The DIVISION Operation:
	The party of the on
	the projects that John Smith works on".
	step 1: Retrieve the list of project no-s - that 'John Smith'

NEHRU COLLEGE OF ENGINEERING AND RESEARCH CENTRE KERALA

SERIES TEST - I

CS 208: Principles of Database Design

Year / Semester & Branch : II / S4 B.Tech. Computer Science & Engineering

Time: 90 Mins Max. Marks: 20

PART-A

Answer ALL Questions $(3 \times 2 = 6 \text{ Marks})$

- 1. What are the responsibilities of DBA?
 - 2. What is Meta data?
 - 3. List out different types of Database languages.

PART- B

Answer ALL Questions (2 x 7 = 14 Marks)

4. Discuss the main characteristics of the database approach and how it differs from traditional file systems? (7 Marks)

OR

5. With the help of diagram explain three schema architecture of DBMS?

(7 marks)

6. Explain different steps in mapping E R Diagram into Relational Schema

(7 Marks)

7 a. Define the following terms: a) Super key

b) Candidate Key

C) Primary Key

(3 Marks)

b. Explain Integrity Constraints.

(4 Marks)

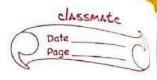

Form No. AC 05

Effective Date: 25.07.201

	-> Security & authorization
	Donain Types:
	-> cheer(n), varcher(n), int, numeric, float etc.
	Schema Definition in SQL:
	* Create table command.
	create table r(A,D, A2D2, An Dn, / integrity Constraint,)
- 1	<integrity constrainty);<="" th=""></integrity>
	Eg: create table customer (come cher(20), Cotacet cher(30),
	* Insert command: to local data into the relation
	Eg: insert into account values ('A-101', Pridge', 1200)
	* delete command: delete tuples from a relation.
	Eg: delete from account;
	* desp command: To remove a rel from ansqu
	db.
	Eg: drop table v; // remone relation v.
1.5	* alter table: to add attributes to an existing
	Relation.
	Eg: alter table & add AD
	where or is the name of an existing relation,
	where of the name of an existing relation, A is the name of the attribute to be added, and D
	is the acomain of the capital attribute.
1	· => attalter table or deop A; where or 19 the
	name of an existing relation, & A is the name of an
	attenbute of the relation. where
	- The harmonic colors of the c
	a he so exercises the field substitute of their

Basic Structure of SQL Queries: -> consists of 3 clauses: select, from and * The select clause corresponds to the projection operation of the relational algebra. It is used to list the attributes desired in the result of a gray. * The from clause corresponds to the Coatesian product opr of the relational algebra. It lists the sells to be scanned in the evaluation of the exp * The where clause corresponds to the selection predicate of the relational algebra. It consists of a predicate involving attendutes of the reins that appear in the from clause. A typical Stop query how the form select A, Az -- An from 81,82 --- 8m where P Relational Algebra Eseps: TIA, Az --- An (Op (7, X72 X --- 7m)) => The select clause: Eg: Find the names of all branches in the loan relationselect brench-name from boan *Elimination of duplicates: Eg: select distinct branch. name from Loans not semoned. * all: to specify explicitly that diplicates are Eg: select all branch name from loans

Scanned with CamScanner

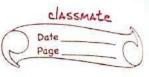

-> 'x' can be used to denote "all afterbutes".

select x indicates that all attendutes of all relater

appearing in the from clause are selected.

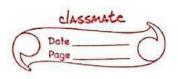

The select clause may also contain authoretic expressions involving the operators +,-, * & / operating on constants or afferbutes of types. Fox eg: select Ino, brame, amount x 100 from loan will sotrem a sel That is the same as the loan relation, except that the attendute amount is multiplied by 100. The where Clause: Eg: Find all lno.s for loans made at the Pridge bromb who with loan amosts > \$1200. · select loo from Lan where b-name = 'Pridge' and amount > \$ 1200 Logical Connectives: and, or, & not. The operands of the logical connectives can be expressions involving the compalison operators to c <, <= , >= , = = = = <> between -comparison operator: Eg: select los from loan where amount between 90000 and 100000. instead of sdect los from loan where amount <= 100000 and amount>= 90000 > The from Clause: Relational_algebra expression Trame, Ino, amount (borrowel Mloan) for the query For all customers who have a loan from the bank, find their names, loan numbers, and loan amount." select c.name, borrower. Ino, amount from borrower, loan where borrower. Ino = loan. Ino

	=> The Rename Operation:
	as clause: used for senaming both selations; -
	attributes.
	old name as new-name
-	For en: if we want the attribute name in to be
	replaced with the name lid, we can rewrite the prece-
500	ding query as
	select Cname, borrower. Ino as lid, amount
	from borrower, loan
	where borrower. I-no= loan. I-no
	=> Texple Variables:
	Eg: For all customers who have a loan from the
	bank, find their names, boan numbers, and boun amont
	as the start of the second while
18	select cname, T. Ino, S. amount
.1	from borrower as T, loan as S
	where T. lno = S. lno
	-> String Operations:
	* leke operator for pattern matching.
	* percent (%): The % character matches any substring
	* Under score(_): The _ character matches any character
	Egs: 1 perry % matches any string begining with "perry".
	"%idge" matches any string containing "idge" as
	a substring, for eq: 'Perryridge', 'Rock Ridge 1 & (Ridgeway)
	a substring, for eg: 'Perryridge', 'Rock Ridge! & 'Ridgewy' *!' matches any string of exactly 3 characters
	* 1% mentches any string of atleast 3 characters
	and the construction of the state of the sta
	Eg: Find the names of all on customers whose street
	adde includes the substring Main.
	Orgon: select coame
	from customer
	where C-street like ' % d Main %'
-	

	escape character:
	the transfer of the transfer o
	NOTE AND THE PROPERTY OF THE PARTY OF THE PA
	SQL allows as to search for mispatches instead of by using
	the not like comparison operator.
	>upper() & lower()
	-> Ordering the Display of Tuples:
	- The order by clause causes the tuples in the
	result of a query to appear in sorted order.
	Eg: To list in alphabetic order all customers who have a
	loan at the Pridge branch
	select distinct c-name from borrower, loan
	where borrower. In o = loan. Ino and b name = Pridge
	order by C-name;
	By default, the order by clause lists items in
	ascending order. specify desc for descending order & asc
	for ascending order.
	Set Operations
	* Onion (Relational Algebra U)
	* intersect(") n)
	* except. (- 11 -)
	2 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1
	1. The Chion Operation:
	Eg: To find all the bank customers having a loan, an
31	account or both at the bank,
)	(select c-name from depositor)
3.5	The upon to sum paydoins the a call of
	(select c-name from borrower)

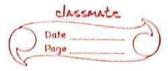

The union oper aliminates duplicates. If we wan to
retain all duplicates, union all in place of union.
(select c-name from depositor)
union all
(select c-name from bosrower)
2. The Intersect Operation;
Eg: To find all austomers who have both a loan and
an account at the bank.
(select distinct c-name from depositor)
intersect and at part of
(select distinct c-name from borrower)
If we want to retain all duplicates, unite intersectal
in place of intersect.
(select cname from depositor)
intersect all
(select c-name from bossower)
3. The Except Operation:
Eg: To find all customers who have an account but no
loan at the bank.
(setect distinct C-name from depositor)
except
(select c-name from borrower)
If we want to retain all deplicates, write except all
in place of except
(select c-name from depositor)
except all
Cselect crame from borrower)
Aggregate Functions:
SQL offers 5 bult-in aggregate functions
Average: avg, Minimum: min, Maximum: max, Total: sum, Cautin
The input to sum & any must be a colly of now.
and the second second

Eg: Find the average account balance at the Pridge branch select avg (balance) from account where b-name=Pridge If we want to apply the aggregate In not only to a single set of tuples, but also to a group of sets of tuples age group by clause. The attribute / attributes given in the group by clause are pt used to form groups. Eg: Find the average account balance at each branch" select b-name, any (balance) from account group by b-name To eliminate duplicates select b name; count (distinct cname) from depositor, account account acens quesides is so perfeamends by quarg members, inhaving clause: which & mosuragmon ter salam Eg: branches where the average account balance is more than \$1200. This condition does not apply to a single tuple, it applies to each group constructed by the group by clause. To express, we use the baving clause. soph applies predicates in the baving clause after groups have been formed. set monotoushup. select b-name, any Chalance) from account group by bename having ang (balance)>1200.

If a where clause & having clause appear in the same query, 89L applies. The predicate in the where clause first. Tuples satisfying the where predicate are then placed into groups by the group by clause. 89L then applies the having clause, if it is present, to each group; it removes the groups to generale hiples of the result of the query.

Eg: Find the average balance for each customer ako lines in Hacuson & Ras al least 3 accounts. select depositor. chame, any (balance) from depositor, account, constomer where depositor account account account and depositor. c-name - customer. c'hame and c-city = Harrison 1 posses all bail ip? group by depositor. aname having count (destinct depositor occord) >3 (Nested Bubqueries: 1) 2) 8 A subquery is a select from where expr that is rested within another query. A common use of subqueries is to perform tests for set membership, make set comparisons & determine set cardinality. * Set Membership with whomand :p3 SCOL allows testing tuples for membership in a relation. The in connectine lests for set memberly where the set is a coll of values produced by a select clause. The not in connetine tests for the absence of set membership. . Ismint med avail Eg: Find all the customers who have both a loan & an account at the banks town min select distinct chame from bossower where coname in (select coname from depositor) Eg: Find all customers who do have a loan at the bank but do not have an account at the bank select distinct c-name from bossower akere c name not in Coclect c-name from deporter group; it remains the groups to generale hip as of

Eg. The sames of customers who same a loan at the bank and whose names are neither Smith nor Jones. select distinct coname from borrower where chame not in ('Smith', 'Jour') * Set Comparison: han land to compare sets, Eg: Find the names of all branches that have assets greates than those of atte alleast one branch located in Brooklys. select distinct T. b-name from branch as T, beamhas S where Trassets > S. assets and S. branch city= Brooklyn'. * Test for Empty Relations: >testing whether a subquery has any tuples in its result. The exists construct returns the valuetive if the aig. subquery 18 nonempty. I diese Eg: Find all wistomers who have both an account & a loon at the bonk anso roting is well select c-name from boxlawer where exists (select * from depositor where depositor c_name = bossower-c-name) * Test for the Absence of Duplicate Tuples: - testing whether a subquery has any duplicate hiples in its result. Eg: Find all customers who have atmost one account at the Per Pridge branch as we had but I select T.C. name from depositor as T where anique Cselect R.C. name from account, depositor R where T. c-name = R. c. name and R. acc-no = account acc-no and account b-name = Reidge) explicitly as follows: essate you provate total Lover (arome, total low as select b rame, sundamount From loan group by b rame.

The mond of without is in Views! Is notion to immer adl Sewerty consideration may require -that certain date be hidden from cisers. Eg: A peru has no need to see the loan amount. Any relation that is not part of the logical model but is made visible to a uses as a visital relation is called a view of a for south made retory in Bucklys. View Definition: - view in sqL by the using the create where T. assets S. assets and S. benommas was the create view Vas(query expression) where Lquery expression) is any logical legal query exps. Eg: create view alleus tomes as Tiller (select b-name got name pare. pro el for Eg: From depositor, account will bail: 83 where depositor.acc-no= account acc-no) select a name from to wave nounverists (solect & Coelect biname, Cname, voltages month from bossower, loan powhere borrower Lno = loan. Lno) Once defined a view, use view name to refer to the vertual relation that the new generales Eg: Find all customes of the Pudge branch select of come frames To below from all customers upon ande where brame = Pudge" The attribute names of a view can be sperified explicitly as follows: Eg: create view browsh total lour Chrame, total low as select 6 name, sum (amount) From loan group by b-name.

Certain db s/ms allow view relations to be stored, If the actual relations used in the view defor change, the view is kept apto' date. Such views are called materialised views. The process of keeping the view aptodate is called view maintenance. Views Defined by using Other Views: One view may be used in the expr. defining another view. Eg: create view Pridge_customer as constraints of referenciamental selections traints are mortered proces - from call-customer co to some losses where b-name = "Pridge" where all-customes is itself a view selation. View Definition expansion is a way to define the meaning of views defined in terms of other views. The view definitions are not recursine le; no view is used in its own defor For eg: Vissued in the defrop V2, vy is used in def of v3 & v3 is used in the the defo of v, then each of VI, V2 EV3 is recuesive. Eg: for View expension bile is my future mode fic good to from white time Perialge constomer whole Chame - John' New eaponston; select & from (select C-name from all-customes where be name = Reidge!) where and name = 'John! It then generales select * from Cocket c-name from (Cselect b-name, c-name from depositor, account where depositor accro = account accro) comion

Eselect b-name, c-name from bollowel, loan and I was to where boreower. L-no=loan.l-no)) where b_name = 'Pudge') in wind berdonalor where chame = John', " coir balles of de de de 1111 Assertions sailed const In assestion is a predicate expressing a concletron that the db always to satisfy Domais constraints & referential Integrity constraints are special forms of assertions. There are many constraint That we cannot express by using only these special forms. Eg: The sum of all loan amonts: for each bronk must be less than the sun of account balances at the branch for one are most wife as a will An asserbon in 80L takes the form acate assertion Lassertion name check (predict When an assertion is created, the s/m lests it for validity of the assestion is valid, then any future modifien to the dk is allowed only if it doesn't cause assestion to be violated. Fox eg: to specify the constraint that "the salary of an employee must not be greater than the salary of the mage of the dept that the employee works for" create assestion salary-constraint check (not exists (select * from Employee E, Employee M, Department Decemp med + where E. salvey SM. salvey and E. DNo = D. D. Number and D.MGRSSN=M-SSN). The constraint name salvy constraint 13 followed by a cond in paramithesis that must hold true on every de database state for the assertion to be satisfied.

Scanned with CamScanner

For eg: to restrict the values of dept numbers to an integer no. b/w 1 & 20, we can write the follo. create Domain D. Nam as integer check (D-Num) and D-NUM (21); Views Continuation View Implementation: & View Update: Query modification: involves modifying the view query into a query on the underlying base tables. Disadv: time Consuming to execute; if multiple queues are applied to the view within a short period of time. View materialization: physically enaling a temporary view table when the view 18 first queried & keeping that table on the assumption that other queries on the view will follow. Create View works-on1 as select Frame, L. Name, P. Name, Hours from Employee, Project, works-on where SSN = ESSN and PNO= PNumber; 4)0x 128001 FName | LName | PName | Hours Update works on 1 set PName = Product Y' where LName = 'Smith' and FName = 'John' and PName = (Product X'; This query can be mapped into several updates on the base sel's to give the effect on the view. Opdate Works-on Set PNO = Sech Select PNumber from Project where PName = ' Producty') when ESSN IN (select SSN from Employee where and pNO In (select Phumber from Reject where Prame = 1 Perchety)

(6) Update Project set prame = 'Product Y'
where Prame = 'Product X';

Paragers:

Triggers are stored pgms, which are automatically executed when some event occurs. Triggers are written to be executed in response to any of the follo events. A db manipulation struct (delete, insert or update); A DDL struct (create, alter or Drop). Triggers would be defined on the table, view, or db with which event is associated.

update causes the trigger to execute.

Eg: create trigges overdraft-trigges after updets of balance on account.

on updates to balance; updates to other attributes would not cause it to be executed.

The referencing old sow as clause can be used to create a variable storing the old value of an updated or deleted low. The referencing new sow as clause can be used with inserts in adolption to updates.

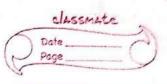

is another eg!, suppose the value in a phose field of an inserted tuple is blank, which indicates absence of a phone no. We can define a suggest the replaces the value by the null value. The set start can be used to carry out such modifiers.

create tegger setnull_trigger before update on & Referencing new row as n row

when nrow.phno = 1 1
set nrow.phno = null;

In the case of RDBMS, design, Eminimize the redundancy, the data has to be organized by decomposing relations to produce smaller well structured relations. This process is called Normalization.

The main phlms in db design are - Redundant Info in tuples

- Update anomalies.

Redundant Info in tuples.

compound of a tople conquely

Bolate, Address, Dno, DName, DMgr8SN)

EName SSN Boate Address DNO DName DMgrssN

Smith 123 1965-1-9 Houston 5 CSE 455

John 134 1955-12-8 Pridge 5 CSE 455

Joyce 3145 1968-7-19 castle 1 ECE 888.

The main goal of db design is to reduce the storage space By grouping the attributes, storage space can be reduced.

Department (DName, DNumber, DMgrNo)

Anomalies:

In the ob. For eg: Consider the above table EMP. DEPT

Shedent Courses (Sid, Iname, phone, Its not possible to

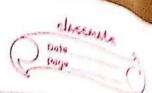

insert a new department details that has no employees as

yet in the relation. The only way to do this is to place null

values in the attributes for employee. This causes a plan ble

ssn is the primary key of EMP. DEPT & each tuple is supposed

to represent an employee entity—not a department entity.

	Deletion Anomaly: Consider the table EMP-DEPT OF
	If we delete from EMP DEPT an employee duple that in

Armstrong's Asicons (Inference Rules for FDS.)

F = {SSN-> {ENAME, Bilate, Address, Dro}, DMumber -> [DName, DMyr SSN]} we can infer the follo addnal FDs from F: SSN→ [DName, DMgrssN], SSN -> SSN, Datumb ONoumber -> DAtime Inference Rules (IR) IR, Creflexine sule). If X 2 Y, then X->Y. Lej . can be stated as X > X; Le; any set of attributes finally determines itself. Proof: Suppose that X DY & that 2 typles to \$ to exist in same relation instance or of R such that to [x]=ta[x]. Then 4 [Y] = to [Y] b/c X 2Y; hence X->y must Rold in o. IR2 (augmontation rule): {X->Y} = XZ->YZ (Bycontradick) 1R3 (transhine sule): [x->Y] + Y->Z] = X->Z. Proof: same 184: (decomposition, or projectine sule): [X-YZ] = X->Y Proof: X->YZ (girus) YZ->Y (wing IR, &YZ ZY) X->Y (cusing 1R3) 1Rz (union or additive sule): [x->y, x->z] = x->>z Proof: Curing IR, through IR3) XX->XY (wing 1R2) @ XY→YZ (wing 1Rz byayminhig willy) X->YZ (wing 1Rs on 384)

in Franch wefored from E.

IR6 (pero pseudotransitiva sub): [X->Y, WY->Z] = WX->Z Proof: X->Y, WY->Z given. @ WX > WY (IR2 augmenting with W) WX->Z (IR3 on 263) Closures (Ft closure) Definition: Set of all dependencies that include for will as all dependencies that can be inferred from F 18 called The closure of F. denoted by Ft Algorithm Determining Xt, the closure of X under cold x+ := x*; for each FD Y->Z in F. do if x+2 y then x+ = x+UZ X 180 (aug number to me () : (+xblo = x) ldm- 2 Consider the Rollo from table EMP-PROJ F= [SSN -> ENorme, PNumber -> [PName, PLocation] (SSN, Prumber -> Hours 3 SSN 3+ = S. SSN, Frame or SV X : from ? PNumber ? = ? PNumber , PName, PLocation 388N, PMinsbar ? -> [58N, EName, PAtimber, PName, Ploudy from the Alexand Equivalence of FDs.VEX NINTE Cover: A set of FDs F 15 said to cover another FD E if every FD in E is also in Ft. le; if every dependent In E can be inferred from F, then E 18 covered by F. Equivalent: Two sets of FDs E & F are equivalent of Et=Ft. Le; every FD in E can be inferred from fit every FD in f can be inferred from E.

Minimal Cone (Minimal Sets of FDs).

A set of functional dependancies F is minimal if it satisfies the follo. conditions:

1. Every dependency in F has a single attribute for its

dependency Y-> A where Y is a proper subset of X, & still have a set of dependencies that is eqt. to F.

3. We cannot remove any dependency from F and still have a set of dependences that is egt. to F.

Normalization using FDs.

→ a process of analysing the given relation scheme based on their FDs and primary keys to achieve the desirable propases of 1. minimizing redundancy & and 2. minimizing the insertion, deletion & applied anomalies.

Adelitional properties: lossless join or non adelitive join property, which guaremters that the spurious tuple generation plan does not occur.

Dependancy preservation: ensures that each FD 13 Represented in some individual rel's resulting after decomposit.

prime attenbute & non prime attenbute:

Prime attribute: it is member of some conscholate key

of R.

non prime attribute: if it is not member of condidate by

of R.

Eg: works on SEN PNO Hours

-	
2	

EMP DEPT not in BNF bk DMGRSSN is fromsitively dependent on ENG -through DNcmber. Boyce-Codd Normal Form It eliminates all redundancy that com be based on functional depondencies. Definition: A relation schema R is in BCNF wirto a set F of FOS if all FDS in Ft of the form X->Y, where XCR & YCR at least one of the follo. Rolds. i) X-> Y is a trivial FD (u; X = Y) ii) X 18 a superkey for schema R. [ENO, EName] -> [EName] (ENo, EName) -> DNo (ENO, EName) -> Salary ENO, EName? -> Hours. Trivial Functional Dependency: A trivial FD 15 a FD of an attendate on a superset of itself. [EID, EAaddress] > [EAddress] 13 trivial 6/c
[EAddress] > [EAddress]

Lossless & Dependency preserving decomposition.

If each FD X->Y specified in F either cotton directly in one of the relation schemos R; in the directly in one of the relation schemos R; in the directly in some Ri. - This is the dependences that approximate want to preserve the dependences of each dependence in F represents a constraint on the do.

A decomposition $D = \{R_1, R_2, \dots, R_m, \}$ of R_1 :

dependency - preserving write F if the union of pupils

of F on each R_i in D is equivalent to Fle; $T(R_i(F)) \cup \dots \cup (T(T_{Tm}(F)))^{+} = F^{+}$

Algorithm: Relational Bynthesis alam with dependency preservation.

Input: A universal Relation R and a set of FDs Footh

1. Find minimal cover G for F (use Algm)

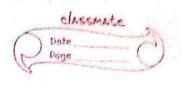

2. For each LHS X of a FD appears in C, carate a

Relation schema in D with attributes \(\text{X U [Ai] U [Az] - 160} \)

Where X \(\text{A}_1 \) X \(\text{A}_2 \) \(\text{X} \) \(\text{A}_1 \) \(\text{A}_2 \) \(\text{A}_2 \) \(\text{A}_2 \) \(\text{A}_3 \) \(\text{A}_4 \) \(\text{A}_5 \) \(\text{A}_4 \) \(\text{A}_5 \) \(\text{A}_6 \) \(

Lossless Joins (Non addition) & Deomposition

has the logs ess (nonaddrine) to in property winto the set of Rependencies F on R if for every relation state or of R to satisfies F, the following holds, where * is the natural of all the relations in D.

 $*T_{R}(\gamma),...T_{Rm}(\gamma))=\gamma.$

If a decomposition doesn't have the loss less join property we may get additional spurious tuples outles the Project (TI)
and Natural Join (+x) operations are applied; these additional tuples Represent erroneous informs.

Algorithm: Testing for the lossless (nonadolitine) to in peoperly. Input: A universal Relation R, a decomposition D={Ri, R2, Rm of R & a set of FDs.

1. Create an initial matrix 8 one low i for each relation Ri in D & one column of for each attribute Aj in R.

2. Set S(i,j) := For all matrix entires.

(* each by is a distinct symbol associated with incline (iji)))

3. For each low i representing relation schema Ri

Efor each column j' representing attendet Ai Eif (Relation R; includes attribute Ai) then set

8(yj):=ajj);?; 4. Repeat the follo loop until a complete loop execution results in no changes to .S.

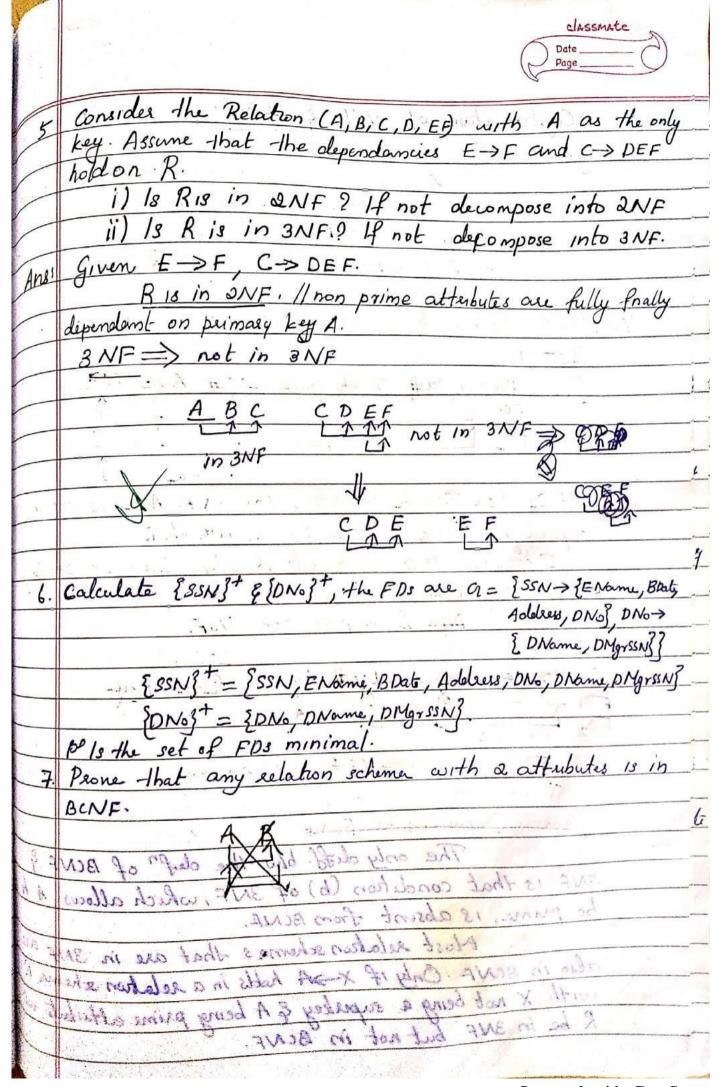

for each FD X->YIN F I for all rows in 5 which have the same symbols in the columns comes to attributes in X.

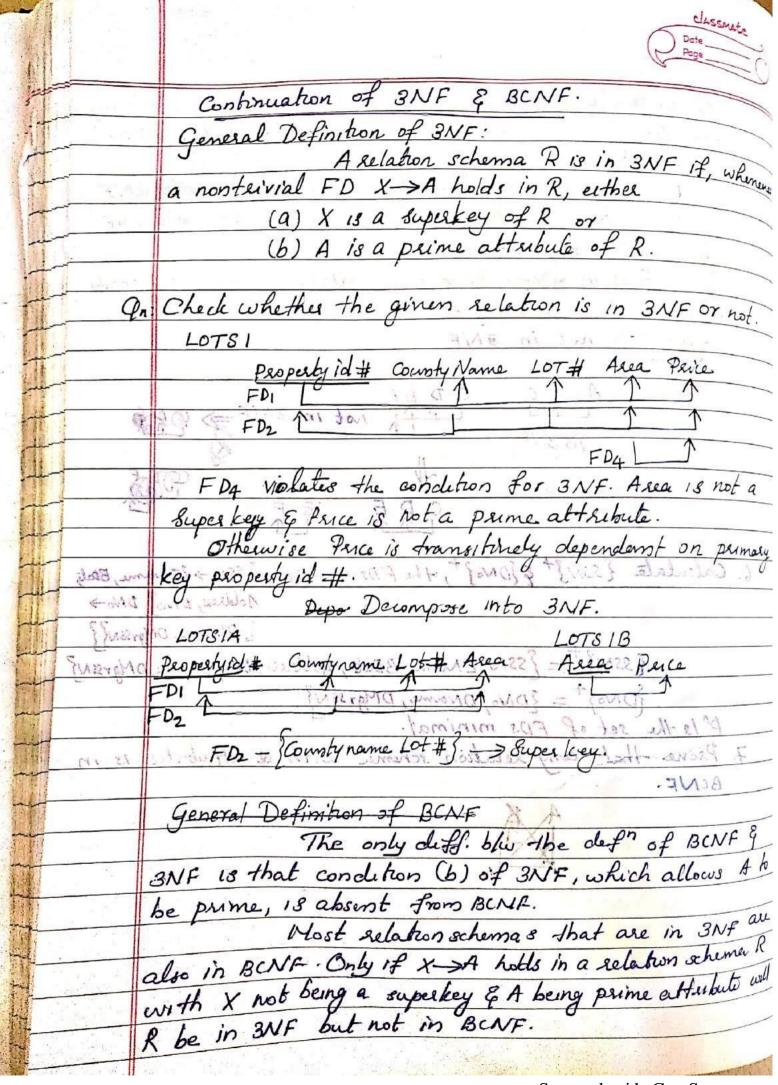

> Emake the symbols in each column that conspond to en attribute in y be the same in all these rows as follows:

If any & of the lows has an "a" symbol for the column, set other rows to the same "a" symbol in the column. If no "a" symbol exists for the afterbute in any of the lows, choose one of the "b" symbols that appear in one of the rows for the attribute & get the other lows to that same "b" symbol in the column ;);)

Appendiction of The St.			Date Page
- Charmen			5. If a sow is made up entirely of "a" symbols, then the decomposition has the lossless join peoperty; o thewere it doesnot.
	4		dispurpos than has the lossless join peoperty; office the

* Clustering Indices

* Multilenel Indices

* B+ Trees Chasic Structure Only, Algms not needed)

> Query Optimization

* Heuristics based query Optimization

1. Consider a file with 200,000 records stored in disk with fixed length blk size 256 bytes. Each second of size 50 bytes. The permerey key is 4 bytes & blk ptr is 6 bytes Compute the follor, assuming multilenel primary inclex is used es access path.

i) Blking factor for data words ii) Bfr for index seconds

iii) No of datables iv) No. of first line index blks.

V) No- of levels of multilevel Index.

Given n= 200,000, B= 256 by tos, Record Size = 50 byte Index Entry R: = 6+4 = 10 by 65.

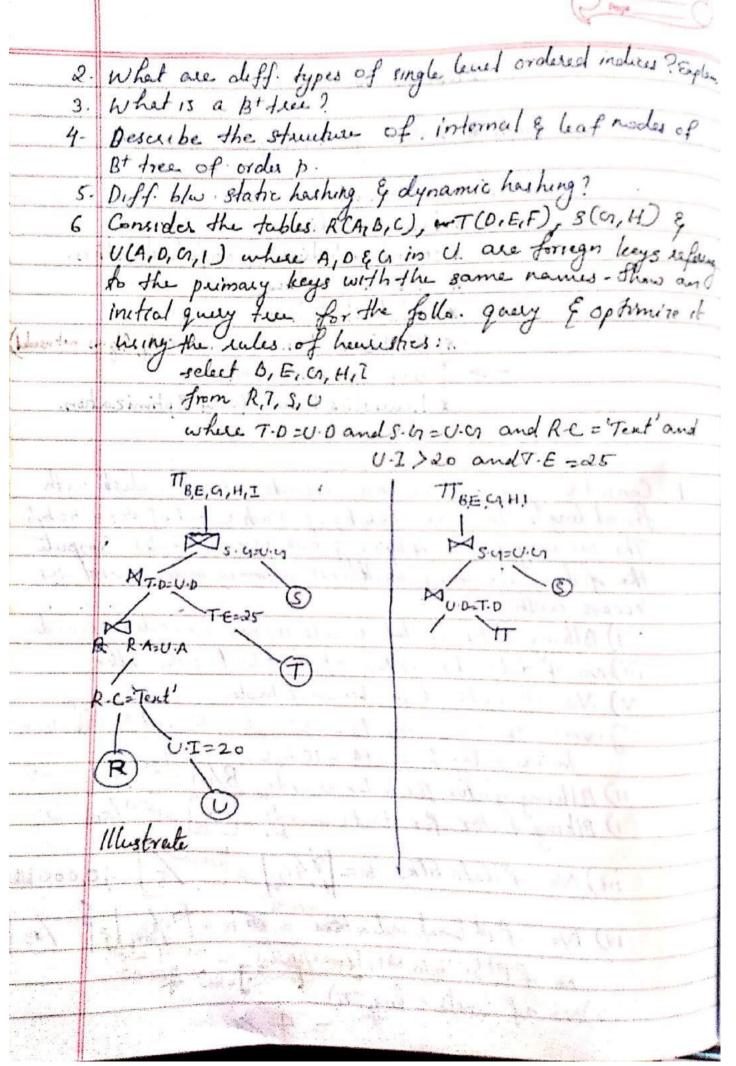

11) Bling factor for Index seconds = B/R: = 256/10 = 25

1) Blking factor for Data seconds = B/B = 256/50 = 5

iii) No. of data blks b= 8/bfr

IV) Nor of 1st level index hos. = 10 bi = 1

No of levels = log, CTI) = [10000/25] = 1600 + 10000 of levels = log cri

Indese Stanctures

A file already exists with some primary org"
such as the amordered ordered or a howhed organizations.

Access structures called indexes are used to speed up the
setrieval of seconds in response to certain search condition.

The index structures provide secondary access paths which
provide alternative ways of accessing the seconds without
affecting the physical placement of seconds on disk.

They enable efficient access to rewords based on the indexy
fields that are used to construct the index.

Single level Ordered Indexes

For a file with a given record structure consisting of iseveral fields (or attributes), an index acress structure is usually defined on a single field or a file, called an indexing field (attribute). The index stores each value of the index of field along with a list of pointers to all disk blks that contain seconds with that field value. The values in the index are ordered so that we can do binary search on the index.

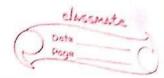

Types of Ordered Indexes:

-> Primary Index -> Clustering Index -> Secondary Index

Primary Index:

Primary index 18 specified on the ordering key field of an ordered file or seconds. Ordering key field 18 used to physically order the file seconds on disk & energy second has a unique value for that field.

length with a fields. The first field is of same data type as the ordering key field - called primary key - of the data fike.

and the second field is a pointer to a disk blk (black address). There is one index entry (or index second) in the index file for each block in the data file. Each index entry has the value of the primary key field for the first second in a blk and a ptx to that ble as its a field values.

a field values of index entry i as (K(i), P(i)) The first 3 index entires are: (KCI) = (Aaron; Ed), P(1) = address of blk 1) (K(2) = (Adams, John), P(2) = 11.19 11-2) < K(3) = (Alex, Ed), p(3) = 11 3) to pir mas and med Fig. B. I wife a Miss It so all The total no of entries in the index is the same as the no. of disk bles in the ordered file. Ach Anchor record/ Block anchor: The first record in each blk of the data file is the -Indexes can also be characterised as dense or spale A dense index has an index entry for every search key value in the data file. A sporse indesc has index enteres for only some of the search values. A primary inclese 18 hence nondense (sparse) inde since it includes an entry for each disk blk of the data file eather than for every search value. The index file for a primary index needs substan trally fewer bles than the data file for a secisons. Is in the are fewer index enteres than there are Re cords in the data file. 2. Each index entry is smaller in size than a det second ble it has only a fields.

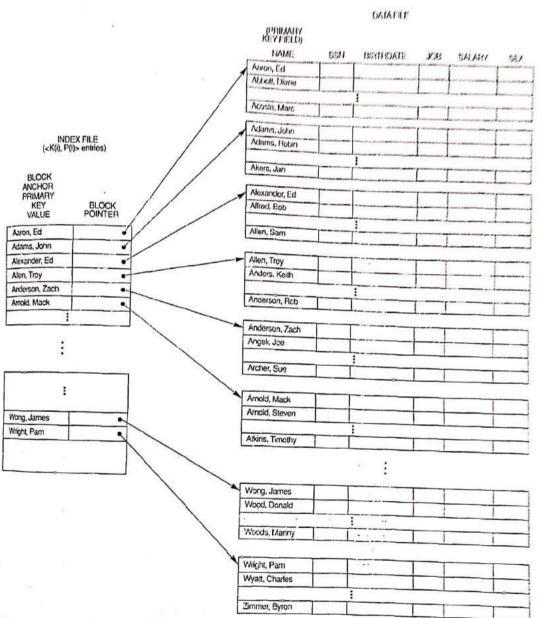

FIGURE 14.1 Primary index on the ordering key field of the file shown in Figure 13.7.

inse

63

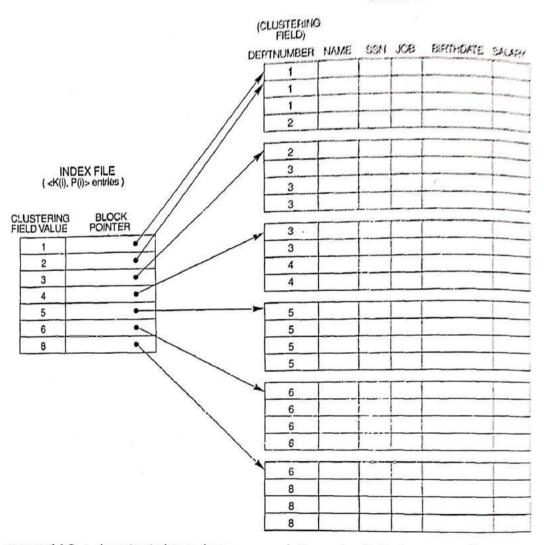

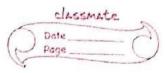

FIGURE 14.2 A clustering index on the DEPTNUMBER ordering nonkey field of an EMPLOYEE file.

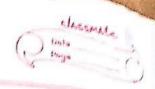

block (or block cluster). This makes insertion and deletion relatively straightforward. Figure 14.3 shows this scheme.

A clustering index is another example of a nondense index, because it has an entry for every distinct value of the indexing field which is a nonkey by definition and hence has duplicate values rather than for every record in the file. There is some similarity between Figures 14.1 to 14.3, on the one hand, and Figure 13.11, on the other. An index is somewhat similar to the directory structures used for extendible hashing, described in Section 13.8.3. Both are searched to find a pointer to the data block containing the

Eq: We have an ordered file with 7 = 30,000 secords stored on a disk with blk size B= 1004 bytes. File se cords are fixed size with second length R= 100 by les. The bling-factor bfr = [B/R] (for the file) = [1024/100 = (1024/100) = losecords/blk. The no. of blks needed for the file b = [7/bfr] = [30000/10] = 3000 blkg. Block accesses (Binary search) = log 6 = log 3000 = 12 blk accesses-Clustering Indexes If records of a file are physically ordered on a nonkey field in that field is called the dus clustering field.

A clustering index is also an ordered file with a fields; the first field is of the same type as the clusterny field of the data file and the second field is a blk ptr. There is one enstry in the clustering index for each distinct value of the clustering field, at the containing the value & a pto to the 1st blk in the data file that hers a second with that value for it's clusterry field. Discolvantage Drawback: -> Record Insertion & deletion Ble dela records are physically ordered. To allendi the plan of insertion, it is common to reserve a wholblk for each value of clustering field AM seconds with that value are placed in the ble . D A clustering index is another eg. of a nondense inden, b/ it has aim entry for every distinct value If the indexing field than for every record in the file. Fig: 6.2 6 6:3

Secondary Indexes

A secondary indese is also on ordered file with a fields. The first field of the same data type as some nonordering field of the data file. That is an indiscing field The second field is bit pla or record pla.

Those is one index entry for each record in the data file, which contours the value of the secondary land for the second & a plr either to the block in which second is stored or to second itsolf. Hence, such an indu

Fig: 6.4. longer search time.

Eq: 8= 30,000, fixed length secords of size R=100 bytes stored on a disk with blk size B= 1024 bytes The file has b= 3000 blks. non ordering key field langth V= 9 by les. ble pts P= 6 bytes long. Calculate blocking factor.

Inclex entuy = V+P = 9+6=15 by 6.5.

Bleng factor bfr = LB/Ri |
(for index) = 1024/15 = 68 entures/blk

The no. of blk needed for the index $b_i = \left\lceil \frac{r_i}{bfr_i} \right\rceil = \left\lceil \frac{30000}{68} \right\rceil =$

HGURE 14.3 Clustering index with a separate block cluster for each group of records that share the same value for the clustering field.

461

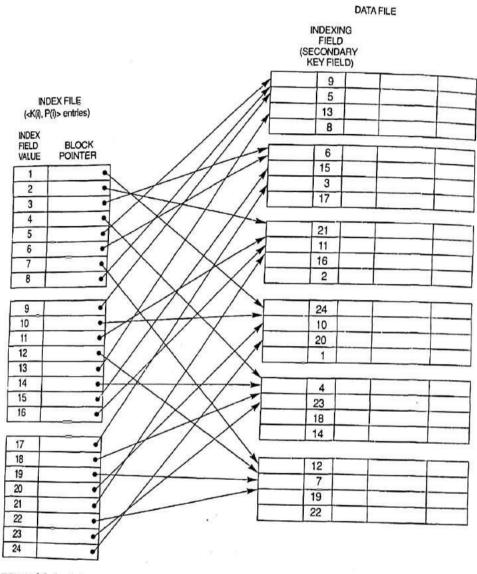

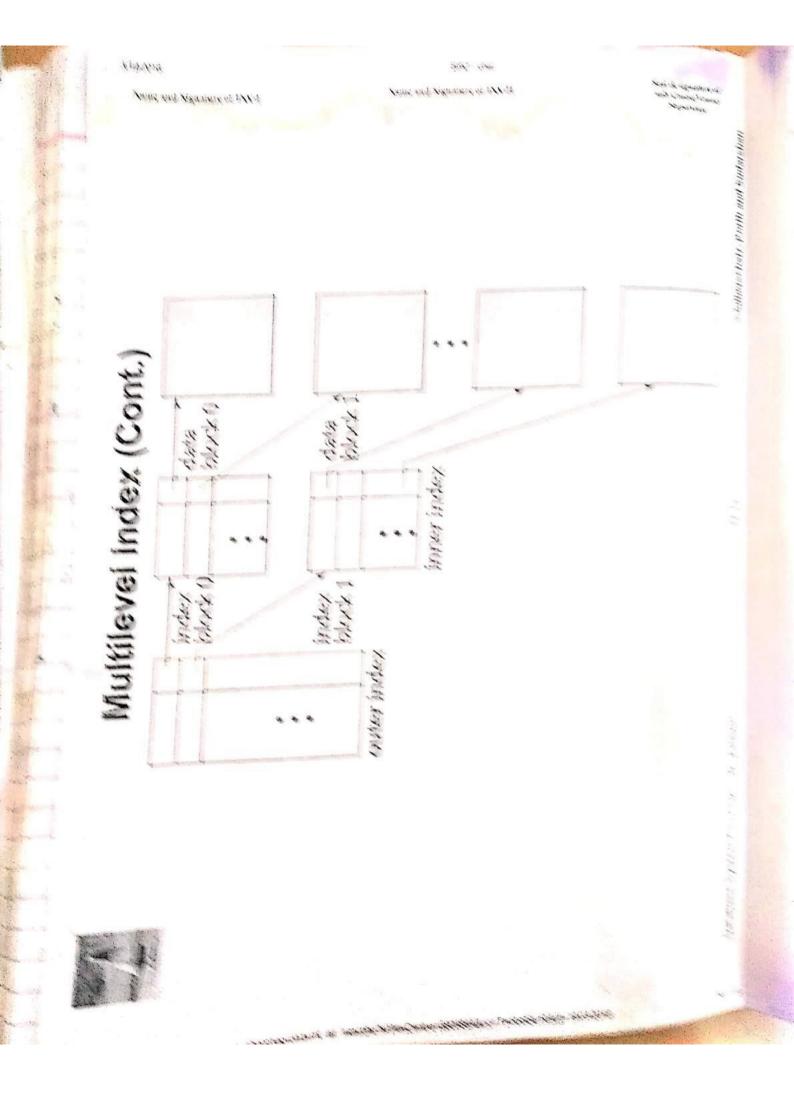

FIGURE 14.4 A dense secondary index (with block pointers) on a nonordering key field of a file.

We can also create a secondary index on a nonkey field of a file. In this case, numerous records in the data file can have the same value for the indexing field. There are several options for implementing such an index:

• Option 1 is to include several index entries with the same K(i) value—one for each record. This would be a dense index.

Multilevel Index

- If primary index does not fit in memory, access becomes expensive.
- Solution: treat primary index kept on disk as a sequential file and construct a sparse index on it.
- outer index a sparse index of primary index
- inner index the primary index file
- If even outer index is too large to fit in main memory, yet another level of index can be created, and so on.
- Indices at all fevels must be updated on insertion or deletion from the file.

Multilenel Indexes

B+ Trees

leaf nodes of tree . The structure of leaf node is diff. from internal nodes.

The leaf nodes have an entry for every value of the search field, along with a data pte to the record is the search field is a key field. For a nonkey search field the ptr points to ablk containing ptrs to the data file herords, creating an extra level of indirection.

The leaf nades of the B+ tree are usually links together to provide ordered access on the search field to the Records. The leaf nodes are similar to the first level of an index.

The structure of theinternal nocles of a B+ tree of order p is as follows!

1. Each internal rode is of the form <P, , K, , P2, K2 - - , Pq-1, Kq-1, Pq>

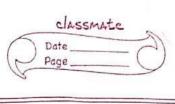

where 9 5 p and Pi is a tree ptr.

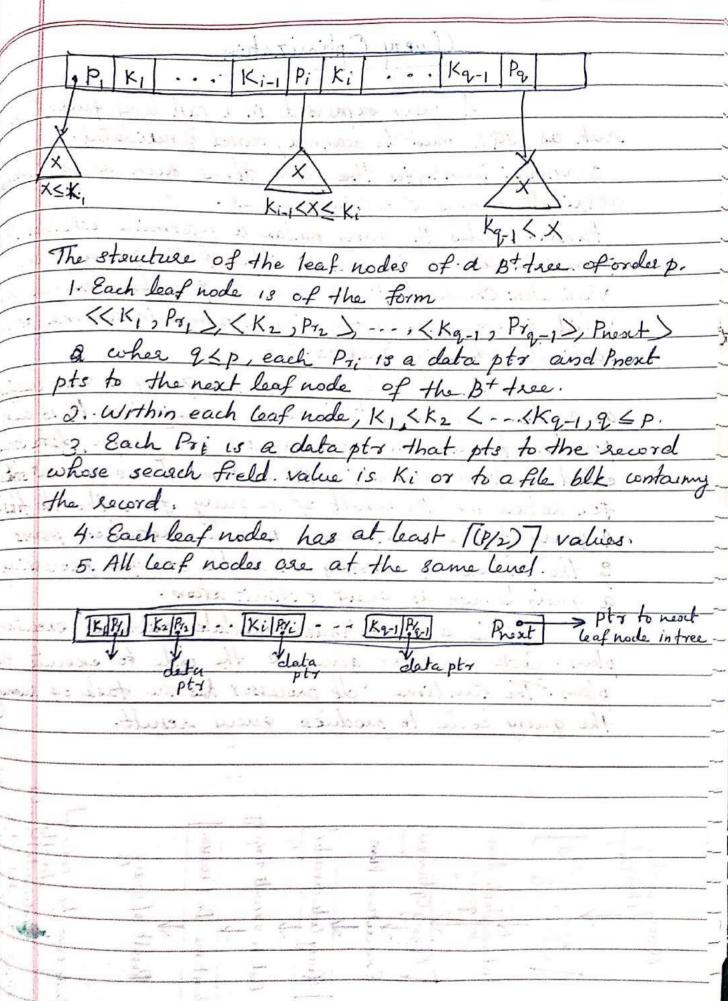

2. Within each internal node, K, K, K. C. Kg. 3. For all search field values X in the subtree pointed at by Pi, we have Ki-1 < X < Ki for 1 < i < 9; X < Kit 1=1; & Ki-1 < X for i=9

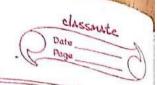

4. Each internal node had at most ptree pointers 5. Each internal node, except the root, has attent

[P/2] tree ptrs. The soot node has atleast 2 tout! if it is an internal node.

6. An internal node with & ptrs, 9 = p has 9-1 seek field values.

Query Optimization

A query expressed in a Righ level query long. such as SQL must be scanned, parsed & validated. I long. Scanner: identifies the long. tolens such as SQL keywood attribute names & relation names.

Parses: checks the query syntax to determine whether it is formulated acc. to the syntax rules of the query long. Validator: checks that all attended & relation names are valid & semantically meaningful names in scheme of the

particular db being quericd.

An internal sept of the query 18 then wested as a true data structure called a guery tree. It is also possible to sepresent the query using a grouph data structure called a query graph. The DBMS then devise an extistion for setueving the result of the query from the db file. A query typically has many possible execution plans of the process of choosing a suitable one for processing a query known as query optimization.

plan. The guery ophinizer module produces execution plan. Code generator generates the code to execute that plan. The run time all processor has the task of running the query code to produce query result.

Translating At Queurs into Relational Algebra.

An spe query is first translated into an eqt. extended relational algebra expression. It is represented as a query tree data steerture. Spe queries are then decomposed into query blks, which form the basic units that can be translated into the algebraic operators & optimized.

A query blk contains a single select- Fromwhere expression as well as group by & having clauses if these are part of the blk.

Eg: select LName, FName

Leons Employee where Solary > (select max (salvey)

from Employee where DNo = 5);

Decomposed toto 2 blks:

man I The inner blk: (select man (salary)

longines 29 where DNo=5)

Outer block: select LName, Frame

How les description from Employee

where salary > C

where a represents the result returned from inner

all blk money & present to

Relational Algebra: Innex blk: Francisalary (DNo=5 (Employer))

outer bille: Thrame, Frome (salary > c (Comploya)).

The guery optimizes then choose an ear plan for each lk. The inner blk needs to be evaluated only once to peoduce the new salary which is then used by the outer blk.

Henristics in Query Ophinization

> Techniques that apply heusestic sules to modefy the internal sept of a query which is in the form of a query tree or a query graph data steneture do impione 143 enpected performance.

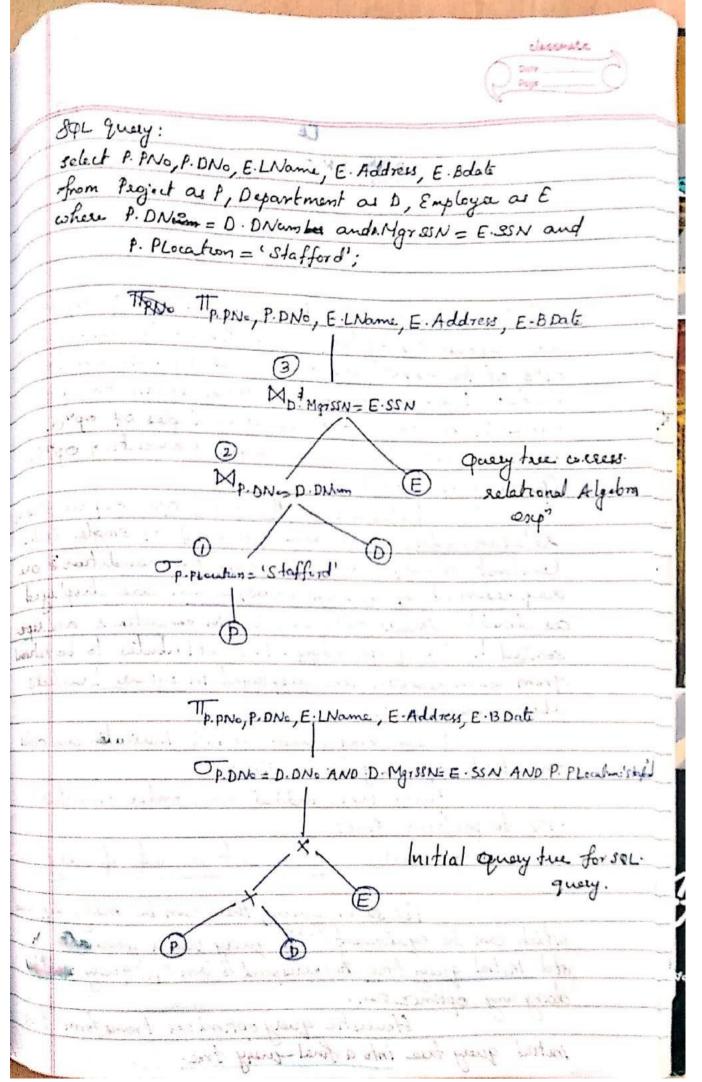

One of the main hereis he rules is to apply select and Pageet operations before appliping the join or other binary op's. This is ble the size of the file resulting from abinary oph such as JOIN 13 woully a multiplicatione of the sizes of i/p files. The felect & Project opres reduce the size of a file & hence should be applied before a join or other binary op?

Notation for Query Trees & Query

A query tree is a tree data staucture that corresponds to a relational algebra expression. It represents the i/p rel's of the query as leaf nodes of the true and represents the relational algebra op's as internal nodes. An ext of the query tree consists of executing an internal node op? whenever its operande are available & then replacing that unternal nocle by the relation that results from executing the op. The ext terminates when the root mode is executed & produces the

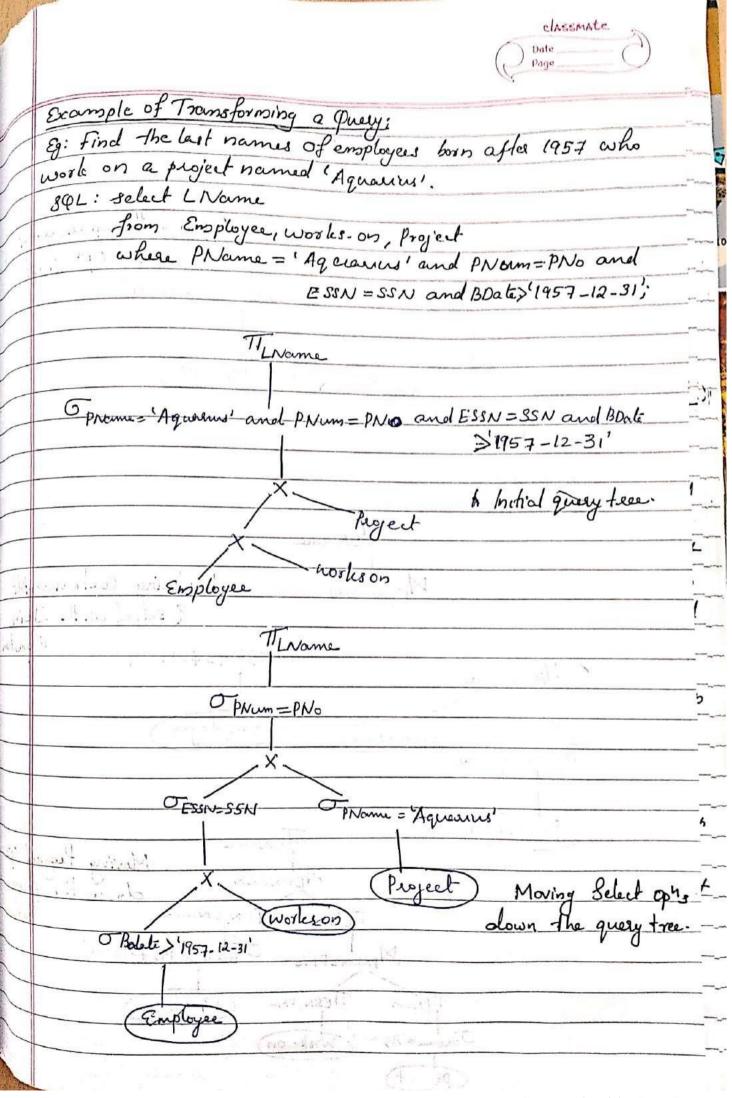

Eg: For every project located in Stafford', returne the project number, the exelling dept no, & the dept rigi's lastname, address & brath Late. Relational Algebra exp?:

Transaction Processing "Concepts:

logical anute of db processing. Transaction processing 3/m3 are slms with large dbs and hundreds of concussent were that are executing db transactions. Eg: 3/ms for reservations, bambing, undit cound processing, stock markets etc.

Transaction includes insertion, deletion, modification or setuieval operations. Be Transaction boundaires are begintransaction & end transaction statements. If the db op's in a transaction do not update the db but only retrieve data, the transaction is called a read only transaction.

A database is borsically represented as a coll" of named data items. The size of a data item is called its granularity. The basic database access operations that a transaction can include are as follows:

reach item (X): Reads a db item named X into a pom variable.

write_item(X): Writes the value of pgm variable X into the db item named X.

Eg: Two Sample Transactions: T, & T.

read item(X); read-item(X)

X= X-N; X= X+M write_item(x); write_item(x);

read-iten (Y):

Y= Y+N;

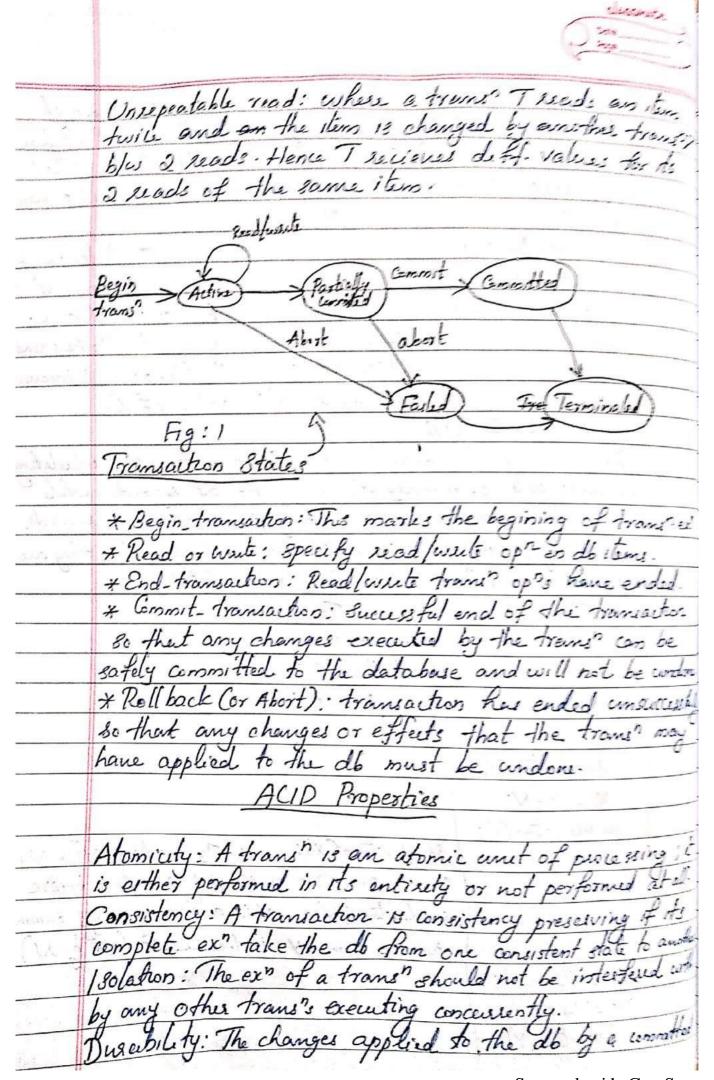

westeritem (Y);

The Last Update Problem: This pb/m occurs when & transm. That access the same db items have their op's interbaned in a way that makes the value of some db item income

1	its opns - optimistic protocols.
1	

Locking Techniques for Concurrency Control

A lock is a variable associated with a cluta item with possible opes that combe applied to it.

Types of Locks & 8/m Lock Tables.

Binary Locks: A binary lock can have 2 states / values:
locked & unlocked (1 or & D). Two op's, lock-items and
unlock_items are used with binary locking. A drawn's yest
access to an items X by issuing a lock-item (X) operation

If hock(X) = 1, the trains 13 forced to went If bock(X):
it is set to 1 & the trains is allowed to access item X.
When the trains 13 through using the item, it issues an
unlock_item (X) op? which sets Lock(X) to o

A binary lock ensures mutual exclusion on the
data tem.

Lock-item (x):

B: If Lock(X)=0 (" I tem 18 cmbocked")

Then Lock (X) (Lock the item)

else begin

the lock my wakes up the trans?).

got to B

Unlock_item (x):

Lock(x) \(-o; ("inlock them item")

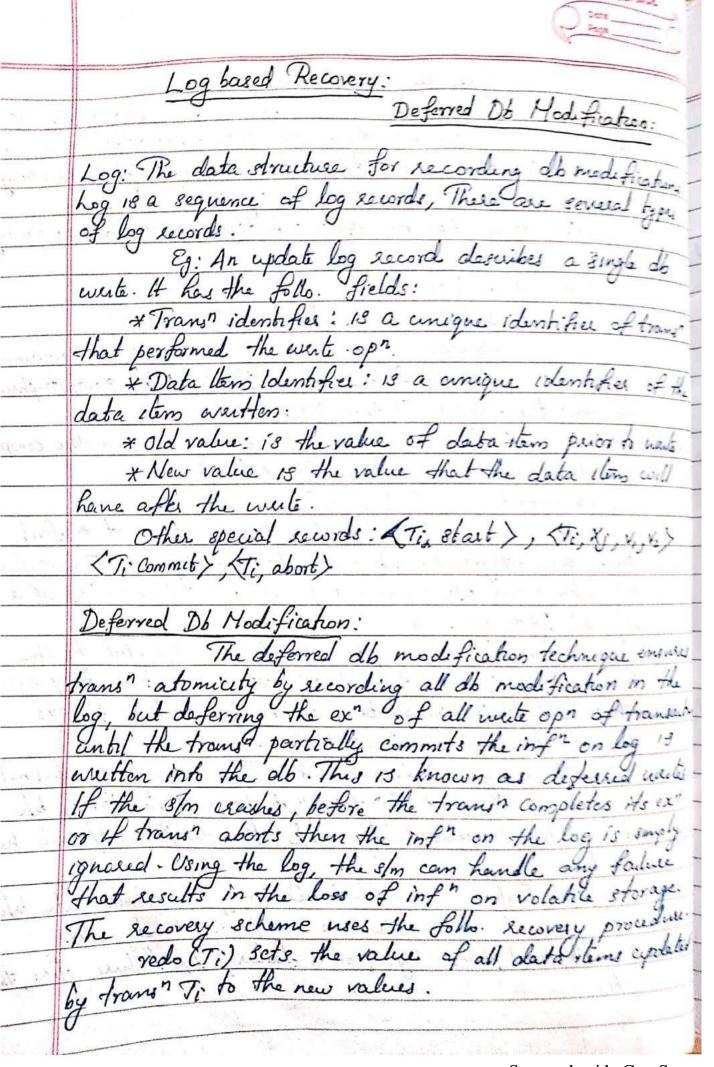

If any trans of one wasting then
wake up one of the wasting trans of,

-	Binasy locking s/m Rules:
-	1. A trans T must issue the ops lock-tem (x) before any
	read item (x) or wester tem(x) ops are performed in T.
-	2 A trans T must issue the op" unlick - item (x) after all
	Read- Item (x) and wester ten (x) opra- are completed in T.
	3. A trans T will not issue a lock-item (x) op- if it
	already Rolds - the lock on tem X.
-	4. A transh T will not seem an unlock stong (x) ophunker
-	it already holds the lock on them y
	-> Shared / Exclusive (or Read/west) Locks:
-	
	Multiple-mode lock: should/Exclusive or read/wite locks: There are 3 locking op's: read-lock (x) write-lock(x) & unlock (x).
	locks: "There are 3 locking op"s: read-lock (x) west-lock(x)
	& unlock (x)
1	hock Compatibility Mature: SX
	S Thue false
_	Eg: // X false false
-	Lock X(B)
-	read B
	B=B-50
	lock X (A) lock on detaitem as per the compatible by read (A) madeix.
	lock x (A) lock on detaiten as per the compatiblely
	lead (A) madeix.
	A = A+60
	weets (1)
1	un bek(A)
	* Conversion of Locks: A trans that already holds
	a lock on item X is allowed under certain cond's to convert
· bion of	the lock from one locked state to another. For eg:, it is possible to for a trems T to issue a read-lock (X) & then
- Line	possible to for a trems T to issue a lead-lock (X) & then
THE RES	later on to upgrade the lock by 185wing a write-lock (X) op
•	later on to upgrade the lock by issuing a west-lock (X) op' If T 19 the only trans holding a read lock on X at the

frme it issues the write-lock (x) opp, the lock can be apgraded; other wise trans must wait. It is also possible for a trans T to issue weitly & then later on to down grade the lock by isswing a read-lock (X) ops. Two-Phase Locking A transaction 18 said to follow the sphere locking peotocol if all locking opns (read-lock, weli-loss precede the first comboch opn in the transaction. Such a framen & can be devided into & phases: > expanding/growing phase, during which no locks on items can be arguised but none can be retained - Shunking phase during which existing locks can be released but no new locks can be acquired If lock conversion is allowed, then upgrading of locks must be done during the expanding phase, & downgrading of locks must be done in the sheinling phoise. Conservatine SPL: Requires framer to lock all the items it accesses before the trans begins ext, by predicte ring its read set & weite set. The read set of a francis the set of all items that the trans reads, & the westest is the set of all tems that it wester Strict 2PL: A trans T doesn't release any of its xlocks (write lock) until after it commets or aborts Rigorous 2PL: Troms T doesn't release any of its late (x lock or shared) custil after it commits or abouts. Deadlock & Starvatus lock X (B) read (B) B= B-50 aute (B) Cocks (A) want & graph.

ليد	
	Failure Classification
	Whenever a transa is submitted to a DBMS for esch
4	the system is responsible for making sure that either
-	1) all the op's in the transaction are completed successfully
	& their effect is seconded permanently in the db.
	a) The trans has no effect whentsover on the db or on any
	other transis.
4	Types of Failures:
	> Transaction failure > Local excors
	-> System Crash Concurrency cy chel enforcement
-	> Disk failure > Physical Polms & catosteophy.
	Scompaler failure (System Crash):
	A K/w or s/w or n/w error occurs in the comp.
	s/m during trans execution. Eq: M/m failure.
	-> Transaction or System error:
3	Some op" in the trans may cause it to fail
-	such as integer overflow or division by zelo. Trans failure
-	may also occur b/c error neous parameter values or b/c of a
-	logical Pgroming error.
2	Logical Pgroming error. Shocal errors or exception conditions detected by the
	transaction: During trains ex', certain conditions may occur
	that necessitate concellation of the transaction. For eg:
	data for the trans may not be found.
93	-> Concurrency ctal enforcement: The concurrency ctal method
-	may decide to abort the trans, to be restarted later, b/
- 3	if violates seculizability or by of a disks read/weste head
- 1	crash.
	> Disk Failure: Some disk blks may lose their data ble
	of readpunte malfunction or readjunte head cross.
	> Physical polms: Eg: power failure, A/e failure, Tike, theft
_	exc. Leading war out of Thereting

Deferred Update in a Single-User Environment

The algor RDU-S (Recovery using Deferred Update in a Single-user environment) uses a REDO procedure, for redoing certain white-item op's; it works as follows:

Procedure RDU-S: Use a lists of drams's: the commit framsachons since the last checkpoint & active trans's Apply the Redo op's to all the write-item op's of the committed drams's from the log in the order in which they were western to the log. Restart the active drams's.

The redo procedure:

Redo (write-op): Redoing a write-item op's western

Redo (write-op): Redoing a write-item op weste-op consists of examining its log entry [weste-tem, T, x, new value] & setting the value of item X in the db to new value, which is the after Image.

in the a Multiuser Environment

Procedure RDU-M(with checkpoints): Use a lists of trows maintained by the 8/m: Ahe committed trains? T. since the last checkpoint (commit list), & the active trans's T' (active list). Redo all the WRITE op's of the commit trans's from the log, in the order in which they were written into the log. The trans's that are active and didn't commit are effectively conceled & must be submitted.

At to, s/m cash:

weite item op's of trango Ti - or any trango committed before the last charlest time by.

Their commit pls affler the last cheep pl.

none of their write-tem ops were recorded in the db

need to be undone, for a reasons:

1. A trans doesn't second any changes in the dh on disk antil after it reaches its commit point - w; until it completes its exa successfully.

2. A trans will never read the value of an item. that is written by an uncommitted trans, ble items remain locked until a trans reaches its commit point.

Checkpointing

Another type of entry in the log 18 called a checkpoint. Alcheckpoint I secord 18 written into the log periodically at that point when the 8/m events out to the alb on disk all BBMS buffers that have been modified. All trans is that have their (commit, T) entries in the log before a Kcheckpoint) entry do not need to have their write op's rectone, in case of a 8/m wash, since all their updates will be recovery magn of a DBMS must during chickpointing. The recovery magn of a DBMS must elevate est what intervals to take a checkpoint.

Taking a checkpoint consists of the follo. actions:

1. Suspend ex" of trans"s temporally. 2. Force - write all main mens. buffers that have being modified to disk. 3. Write a Kcheckpoint > second to the log, & force weste the log to disk. 4. Resume excelling transers. FUZZY Checkpointing The time needed to force-write all modefied memory buffers may delay trans processing ble of step 1. To reduce this delay, it is common to use a technique called fuzzy checkpointing. In this technique the s/m can resume frans processing after the Check point & record is written to the log without Raving to wait step 2. to finish. Until step 2 is completed, the previous <check point > record should Remain to be valid. The 8/m maintains a pointer to the valid checkpoint, which continues to point to the previous (checkpoint) second in the log. Once the Step 2 is concluded. That ptr is changed to point to the new check point in the log.

BFIM: Before Image: The old value of the data ilem before updating.

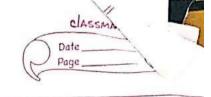

AFIM: After mage => The new value of data tem after updating.

White Aheard Logging: The Recovery mechanism must ensule that the BFILY of the data tem is recorded in the approprial log entry & that the log entry is flushed to disk before the BFILY is overcoutten with the AFILM in the db on the disk

Biological Databases

Biological data exhibits many special characters. stics that make mgmt of biological Int's. Bioloformatics: addresses information mgmt of genetice information mgmt of genetice information mgmt of genetice analysis. 1. Biological data is highly complex when compared with most other domains. Eg: DNA PRNAS. 2. The amount & sange of variability in data is high-3. Schemas in biological detabases change at a rapid pare. 4. Kepresentations of the same data by diff. biologists will likely be different (even when noing the same son). 5. Most users of biological data do not require weete access to the destabase; read only access 13 adequate. 6. Most biologists are not likely to have any knowledge of the internal structure of the db or about schema design. 7. The context of data gives added meaning for its use in biological applications. 8- Defining & representing complex queries is extremely imp. to the biologist. 9. Users of biological inf" often require access to "old" values of the deeta-particularly when verifying previously reported results. Human Genome: Generally refers to the complete set of genes sequised to create human being (100000 to 300000 genes spread over 23 pairs of chromosomes.) Genbank: DNA sequence db in the world is Genbank maintained by the National Costre for Biotechnology Info of National Library of Medicine (NLM)

	The Genome Database (CIDB): (1989) 18 a catalog of
-	human gene mapping data, a process that associates - a piece of info with a particular loca on the human

1	Information Retrieval Query languages And their brief description
	1
2	Latest tools used for ER diagram

1. Information Retrieval Query languages and their brief description

Information search and retrieval involves finding out useful documents from a store of information. In any information search and retrieval system an important factor which plays a role is search and selection process. Information Retrieval System (IRS) allow to find useful documents from a large volume of information by giving a query to the IRS. Information search can be made by presenting a query through the inter-mediator, or directly to the IRS. A query in general terms is a statement or series of statements made by a user to a retrieval system for the purpose of specifying what information is to be retrieved and in what form. Most of the time the query is specified in format such as artificial language hence it is called query language. A query language is the means by which the user tells the IRS what to do and what is wanted. A query is distinct from the types of documents that the user is trying to retrieve. The document and the query undergo parallel processes within the retrieval system. On the document side, someone generates or gathers some data and formulates it into a document. After creating documents they are transferred into internal representation, which then gets transferred into a format that is used for matching process. On the query side, user begins with information needs. There are two broad types of query language procedural and non-procedural or descriptive. A procedural language uses commands. If the query is written in a typical procedural query language often known as command language, little or no knowledge is required for the IRS to find what was asked for and retrieve. Natural language queries or non-procedural queries generally tend to be ambiguous in syntax and meaning. For natural language queries inter-mediator is required to formulate a query as these queries generally tend to be ambiguous. Command language queries are more structured and for IRS these queries are unambiguous.

2. Latest tools used for ER diagram:

Database Design is a collection of processes that facilitate the design, development, implementation, and maintenance of database management systems (DBMS). Properly designed databases help you to improve data consistency for disk storage.

There are a wide range of software that helps you to design your database diagrams with ease. These database design tools can be used to create a physical model or ERD of your database so that you can quickly create tables and relationships.

Following is a list of Database Diagram Design Tools, with their popular features

1. Dbdiagram.io

Dbdiagram.io is a simple database design tool to draw ER (Entity Relationship) diagrams by just writing code. It is one of the free erd tools designed for developers and data analysts.

2.SqlDBM

SqlDBM is one of the best database diagram design tools that provides an easy way to design your database on any browser. You do not require any other database engine or database modeling tools or apps to use this program.

3. Dbdesigner.net

Dbdesigner.net is an online database schema design and modeling tool. This database diagram tool allows you to create a database without wiring a single SQL code.

4. Visual Paradigm

Visual Paradigm is a database design and management tool. This database diagram tool helps the product development team to build applications faster.
